

# The Association between Helicobacter Pylori Infection and Unexplained Subfertility in Women

## Thesis

Submitted for Partial Fulfillment of Master Degree  
in **Obstetrics and Gynecology**

By

**Mohamad Rafik Awad Shahin**

M.B.B.Ch. (2011)

*Resident of Obstetrics and Gynecology  
Bagour Hospital*

Under Supervision of

**Prof. Dr. Mohamed Sayed Ali**

Professor of Obstetrics and Gynecology  
Faculty of Medicine – Ain Shams University

**Dr. Ahmed Mahmoud Hussein**

Lecturer in Obstetrics and Gynecology  
Faculty of Medicine – Ain Shams University

Faculty of Medicine  
Ain Shams University  
**2016**

A decorative frame in the shape of a stylized four-lobed flower or cloud, with a green outline and a yellow-to-white gradient fill. It features intricate floral and geometric patterns in green, pink, orange, and red at the top and bottom. The text is centered within the frame.

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ  
وَاتَّقُوا اللَّهَ وَيُعَلِّمُكُمُ اللَّهُ  
وَاللَّهُ بِكُلِّ شَيْءٍ عَلِيمٌ

صدق الله العظيم

سورة البقرة آية 282

## Acknowledgments

First of all and above all great thanks to **ALLAH** whose blessings on me cannot be counted.

The sincerest thanks, deepest appreciation and greatest admiration to my **Prof. Dr. Mohamed Sayed Ali**, Professor of Obstetrics and Gynecology, Faculty of Medicine – Ain Shams University, for his constructive and keen supervision, Fruitful criticism, continuous support and encouragement to complete this work. I really have the honor to complete this work under his supervision.

I feel greatly indebted to **Dr. Ahmed Mahmoud Hussein**, Lecturer in Obstetrics and Gynecology, Faculty of Medicine – Ain Shams University, for his trustful help, sincere guidance, continuous support and assistance.

Last but not least, I can't forget to thank all members of my **family**, specially my **Parents** and my **Wife**, for their support and care.

Candidate

 **Mohamad Rafik Awad Shahin**

## Abstract

**Objective:** The aims of our study were to investigate the association between unexplained infertility and *Helicobacter Pylori* infection among women attending Ain Shams University Maternity Hospital.

**Study design:** This study was a Case-control observational study conducted in Ain Shams University Maternity Hospital. We analysed *H. pylori* IgG antibodies in the serum & cervical mucus of 34 patients diagnosed with unexplained infertility using CTK Onsite Rapid Test (F1206K3F00) comparing that with 34 fertile women.

**Results:** There was a higher proportion of women with positive serum *H. pylori* antibodies among women with unexplained infertility when compared to control women. However, the difference was statistically insignificant [ $p=0.052$ , OR 2.62, 95% CI (0.98 to 6.98)]. There was a higher proportion of women with positive cervical mucus *H. pylori* antibodies among women with unexplained infertility when compared to control women. However, the difference was statistically insignificant [ $p=0.140$ , OR 2.28, 95% CI (0.8 to 6.48)].

**Conclusions:** Our study demonstrated that no correlation between serum and cervical *H. pylori* IgG and unexplained infertility.

---

**Key words:** *H. pylori* IgG antibodies, unexplained infertility,

---

# Introduction

**I**nfertility is defined as a failure to conceive after at least 1 year of regular unprotected intercourse (*Zegers et al., 2009*).

It affects approximately 10 % of couples in their reproductive lives (*Boivin et al., 2007*).

Unexplained subfertility is defined as infertility without any demonstrable cause after the basic fertility workup, including assessment of ovulation, semen analysis and evaluation of tubal patency. The incidence of infertility is increasing in the developed world mainly due to postponement of maternity. After a basic fertility workup, about 25 % of couples will be diagnosed with unexplained infertility (*Brandes et al., 2010*).

The role of infections as a cause of infertility is well recognised (*Pellati et al., 2008*).

Infectious agents such as Chlamydia, Mycoplasma, viruses and yeasts can impair sperm motility at vaginal, uterine or/and tubal level. In addition, all these agents can induce inflammatory processes and cell-mediated immunological reactions (*Pellati et al., 2008*).

One known cause of infertility is the presence of secretory IgA antibodies in cervical mucus, which can react

with some sperm structures, impairing their motility. Human spermatozoa have antigens that cross-react immunologically with certain microbial antigens of yeasts or bacteria such as Chlamydia (*Clarcke et al., 2009*).

In 1991, Perez-Perez et al. found serum anti-H. pylori antibodies in 17% of 277 couples attending an infertility centre, but both partners were seropositive only in 6.6% of cases. The authors thus concluded that person-to-person H. pylori transmission rarely occurs between young, sexually active adults (*Perez-Perez et al., 1991*).

*Figura et al. (2002)* hypothesised a relationship between anti-H. pylori antibodies and infertility, i.e., that antibodies produced against H. pylori block the sperm tail. The authors found seropositivity for H. pylori infection to be higher in women of couples with infertility than in controls (44.8% versus 29.7%,  $p < 0.001$ ). In addition, follicular fluid from the infected patients contained specific IgG and IgA anti-H. pylori antibodies in all cases. Serum anti-H.pyloriIgG antibodies reacted with the tail, centrioles and equatorial zone of human sperm.

In a retrospective study of 204 patients with unexplained subfertility tested for anti-H. pyloriIgG antibody in serum and follicular fluids, Kurotsuchi et al. reported that 22.1% were seropositive, and concluded that H. pylori

infection may increase the risk of infertility (*Kurotsuchi et al., 2008*).

In another study of 67 patients with unexplained infertility held at university of Padova, Italy, The penetration of normal sperm, in 15 cervical mucus samples positive for anti-H. pylori antibodies and in 15 negative samples, was assessed using the simplified slide test.

A significant positive correlation emerged between anti-H. pylori IgG antibody concentrations in the serum and in the cervical mucus ( $r = 0.9275$ ;  $p < 0.00001$ ). In the 15 anti-H. pylori IgG mucus-positive samples the slide test showed abnormal penetration by the spermatozoa (*Guido et al., 2010*).

The authors concluded that the presence of anti-H. pylori antibody in the cervical mucus can be involved in female infertility, interfering with sperm progression. Considering the close correlation found between serum and cervical mucus anti-H. pylori antibody titres, measuring serum antibodies could become an additional test, in particular in couples with unexplained infertility (*Guido et al., 2010*).

The evidences that *Helicobacter pylori* (H. pylori) infection may have a role in decreasing human reproductive

potential are steadily increasing. Sperm quality of men infected by *H. pylori* strains expressing Cag. A is reduced. Infected women have specific antibodies in cervical mucus, which decrease sperm motility, as well as in follicular fluids, which may cross react with sperm. In women with polycystic ovary syndrome and preeclampsia the prevalence of *H. pylori* infection is increased. The putative pathogenic mechanisms that account for these observations include elevated inflammatory cytokine levels in infected individuals and phenomena of antigenic mimicry between bacterial antigens and human proteins (*Moretti et al., 2014*).

There are evidences that *H. pylori* infection, especially by strains expressing Cag. A, may influence negatively the human reproductive potential. It is generally accepted that one of the mechanisms that may explain the association of *H. pylori* infection with extra-digestive diseases, could reside in the overproduction of inflammatory cytokines, which is a distinctive feature of strains expressing Cag. A. Antigenic mimicry between Cag. A and other bacterial antigens and human peptides could also play a relevant role. Before reproductive disorders could be considered an additional manifestation of extra-digestive diseases associated with *H. pylori* infection, it is necessary to carry out other studies concerning the prevalence of *H. pylori* infection in patients and controls, and in particular to perform study dealing with

evaluation of reproductive potential after eradication of *H. pylori* infection (*Moretti et al., 2014*).

The capability of male gamete to fertilize the ovum is compromised by presence of anti-sperm autoanti-bodies, seminal *H.Pylori* antibodies were detected in (9.87%) of the investigated infertile men with weak sperm motility, this shed a light on that *H.pylori* could be a cause of weak sperm motility. *H.pylori* treatment significantly improves sperm motility in infertile asthenozoospermic men with elevated seminal *H.pylori* antibodies (*Yehia et al., 2014*).

## **Statement of the Problem**

*H. pylori* is a common infection worldwide, the etiological agent of chronic active gastritis and the major cause of peptic ulcer disease and primary gastric lymphoma of MALT type. The difference in the outcome of the disease may be associated with the bacterial genotypes. Also the treatment failure of the bacteria is associated with decreased eradication rate. The exact route of transmission of *H. pylori* is still not well understood. We know that the human body is the only natural reservoir for *H. pylori* and that, therefore, person-to person transmission is the most likely method of transmission a number of factors, such as crowding index, low socioeconomic status (*Fiedorek et al., 1991*), an infected family member (*Blecker et al., 1994*), and ethnicity (*Lanciers et al., 1996*), have all been linked to a higher incidence of *H. pylori* infection.

The evidences that *Helicobacter pylori* (*H. pylori*) infection may have a role in decreasing human reproductive potential are steadily increasing. Sperm quality of men infected by *H. pylori* strains expressing CagA is reduced. Infected women have specific antibodies in cervical mucus, which decrease sperm motility, as well as in follicular fluids, which may cross react with sperm. In women with polycystic ovary syndrome and preeclampsia the prevalence of *H. pylori* infection is increased. The putative pathogenic mechanisms that account for these observations include elevated inflammatory cytokine levels in infected individuals and phenomena of antigenic mimicry between bacterial antigens and human proteins (*Moretti et al., 2014*).
