
**Effect of an Intervention Training Program on
Hospital Acquired Infection Rates in Intensive
Care Units of Governmental Hospitals in Egypt**

*Thesis submitted for partial fulfillment of the
MD degree in Public Health*

By

Ramy Galal Ahmed Ginady

*M.B.B.ch., Master degree of Public Health
Infection Control specialist
Ministry of Health and Population, Egypt*

Under supervision of

Professor/ Mohsen Abdel Hamid Gadallah

*Professor of Public Health and Preventive Medicine
Faculty of Medicine, Ain Shams University*

Professor/ Mohamed Yehia Al Awady

*Professor and head of Public Health and Preventive Medicine
Faculty of Medicine, Ain Shams University*

Dr/ Lamyaa Said Al Bagoury

*Lecturer of Public Health and Preventive Medicine
Faculty of Medicine, Ain Shams University*

**Faculty of Medicine
Ain Shams University**

2016

ACKNOWLEDGEMENT

First of all I would like to praise and thank **GOD** for giving me the strength to finish this work and praying him for more success in my life.

I would like to express my deepest thanks and gratitude to **Professor Dr. Mohsen Abdel Hamid Gadallah** (*Professor in the department of Community, Environmental and Occupational medicine Faculty of Medicine, Ain Shams University*) for his support and his continuous encouragement, motivating me to finish this work.

I would also like to express my profound gratitude and respect to **Professor Dr. Mohamed Yehia Al Awady** (*Professor & Head of the department of Community, Environmental and Occupational medicine Faculty of Medicine, Ain Shams University*) for his useful advice, marvelous efforts and help during this study.

My deep appreciation to **Dr. Lamyaa Said Al Bagoury** (*Lecturer in the department of Community, Environmental and Occupational medicine Faculty of Medicine, Ain Shams University*) for her continuous supervision and her helpful criticism that contributed to the success of this work.

My deep gratitude and thanks to **Dr. Amr Mohamed Kandeel** (*Chief of preventive sector, MOH*) for his great effort in supporting me and supporting the implementation of infection control programme in Egypt as he is one of the pioneers in infection control in Egypt.

My deep thanks to **Dr Mohamed Ginady** (*General Director of Communicable disease control, MOH*) for his great effort in supporting the implementation of infection control programme in Egypt as he is one of the pioneers in infection control in Egypt.

Finally, I would like to express my thanks, gratitude and admiration to **my family** and **my colleagues** for their endless support and inspiration.

Introduction

Nosocomial infection or health care associated infection is an infection acquired in health care facility by a patient who was admitted for a reason other than that infection, this infection is not present or incubating at admission. Infection occurring more than 48 hours after admission is usually considered nosocomial infection (*WHO, 2002*).

Studies throughout the world documented that health care associated infections are among the leading causes of death and they cause significant morbidity among patients who receive health care (*Kim et al, 2000*).

A prevalence survey conducted under the auspices of WHO in 55 hospitals of 14 countries representing 4 WHO Regions (Europe, Eastern Mediterranean, South-East Asia and Western Pacific) showed an average of 8.7% of hospital patients had nosocomial infections. At any time, over 1.4 million people worldwide suffer from infectious complications acquired in hospital. The highest frequencies of nosocomial infections were reported from hospitals in the Eastern Mediterranean and South-East Asia Regions (11.8 and 10.0% respectively), with a prevalence of 7.7 and 9.0% respectively in the European and Western Pacific Regions (*WHO, 2002*).

A WHO study has shown that the highest prevalence of nosocomial infections occurs in intensive care units. Infection rates are higher among patients with increased susceptibility because of old age, underlying disease, or immunosuppression (*WHO, 2002*).

In the USA, the most frequent type of infection hospitalwide is urinary tract infection (36%), followed by surgical site infection (20%), and bloodstream infection and pneumonia (both 11%) (*Pollack, 2010*).

Healthcare-associated infections are serious, common, and important patient safety issues in health care today. Infection prevention is a cornerstone of continuous quality improvement (*Stone et al, 2002*).

Surveillance as an element of epidemiological practice is “the ongoing systematic collection, analysis, and interpretation of health data essential to the planning, implementation, and evaluation of public health practice, closely integrated with the timely dissemination of these data to those who need to know. The final link in the surveillance chain is the application of these data to prevention and control.” This definition is part of the plan for the national coordination of disease surveillance of the Centre for Disease Control and Prevention (*Robert, 2008*).

Surveillance of HAI is a critical component of prevention efforts, particularly in infection control programs newly introduced into hospitals. In the 1970's, the Study on the Efficacy of Nosocomial Infection Control (SENIC) showed that intensive surveillance, in combination with other aspects of an infection control program, was associated with significantly reduced rates of HAI (*Zaidi, 2005*).

A survey conducted by the CDC in 2000 found that an infection control epidemiologist spends 35%–40% of work time performing surveillance (*Nguyen et al, 2000*). A study found that the use of electronic systems reduced the time spent on surveillance by 65% (*Chalfineet al, 2006*). Both commercial and independently developed computer based surveillance systems have the potential to increase efficiency and to reduce economic costs at multiple levels of the healthcare system. There are few peer reviewed studies that explicitly investigate the cost-effectiveness of computer-based surveillance, but at least 2 studies have shown automated surveillance to be significantly cost-effective (*Furuno et al, 2008*). Several individual case studies have found that implementing an electronic surveillance system reduced both infection rates and associated economic costs (*Hess et al, 2007*).

In Egypt, the national infection control (IC) program started in 2003. The strategic plan of the IC program included training and capacity building of staff, creating organizational structure, promotion of occupational safety, monitoring and supervision, and surveillance of HAI. So far, 313 hospitals have been trained on IC standard precautions. However, nowadays a surveillance system for HAIs is ongoing in Egypt, as it is an essential component but till now, there is no governmental national wide laboratory based surveillance data regarding HAIs. The development of such a laboratory based surveillance system is essential to detect hospital outbreaks and improve the performance of the infection control program in the hospitals to improve the quality of health care provided.

Study Rationale:

Since HAI is still a problem in Egyptian hospitals and there is weak knowledge and poor adherence of HCWs to the infection control standard precautions in addition to the presence of weak data on HAI rates in Egyptian hospitals, therefore close surveillance, accurate measurements and conducting an intervention in the form of training of HCWs on infection control standard precautions are essential to reduce HAI rates in Egyptian hospitals to improve the quality of health care provided.

Study Hypothesis

Intervention in the form of training of health care workers on infection control standard precautions including the preventive bundles for each of urinary tract infection (UTI), blood stream infection (BSI) and pneumonia, will reduce HAI rates in the selected ICUs of the study hospitals.

Research Questions

What is the incidence rate of HAIs in the selected ICUs of the study hospitals before the intervention?

What is the incidence rate of HAIs in the selected ICUs of the study hospitals after the intervention?

Will the intervention done in the form of training of health care workers on infection control standard precautions including the preventive bundles for each of UTI, BSI and pneumonia, be effective in the reduction of HAI rates in the selected ICUs of the study hospitals?
