Abstract

PACS (Picture Archiving and Communication System) is an Information management system for archiving and managing images in radiology department .It is a computerized electronic system, which entirely replaces conventional x-ray and hard copy films by acquiring, archiving, transmitting and displaying digital images on a network of workstations throughout the hospital.

DICOM, which stands for Digital Imaging and Communications in Medicine, is a standard that was developed to “promote communication of digital image information, regardless of device manufacturer” within a radiological environment.

Key Words :

Compuete Aided Diagnosis – Cothode Ray Tube – Altrasound .

Acknowledgement

First and foremost, thanks God the most merciful and most beneficent to who I relate any success in achieving any work in my life.

It gives me the greatest pleasure to express my deepest gratitude and warmest thanks to ***Professor.Dr. Sameh A.Z. Hanna*** , Professor of Radiodiagnosis, Cairo University, for his kind supervision and valuable suggestions. Dedicating much of his time and encouraging guidance were the reason for enriching this work.

It seems very difficult to select the suitable words expressing my respect and appreciation to ***Dr. Manal Halim Wahba***, Lecturer of Radiodiagnosis, Cairo University, for her valuable assistance, encouragement and helpful instructions throughout the work.

Lastly, I would like to extend my deep thanks to ***my family*** for their permanent help and support through every step in my life.

Introduction:

With the introduction of computed tomography (CT) followed by other digital diagnostic imaging modalities in the 1970's, and the increasing use of computers in clinical applications, the American College of Radiology (ACR) and the National Electrical Manufacturers Association (NEMA) recognized the emerging need for a standard method for transferring images and associated information between devices manufactured by various vendors. These devices produce a variety of digital image formats. The American College of Radiology (ACR) and the National Electrical Manufacturers Association (NEMA) formed a joint committee in 1983 to develop a standard to:

- Promote communication of digital image information, regardless of device manufacturer
- Facilitate the development and expansion of picture archiving and communication systems (PACS) that can also interface with other systems of hospital information
- Allow the creation of diagnostic information data bases that can be interrogated by a wide variety of devices distributed geographically (**HL7, 2000–NEMA, 2003**).

The digital imaging and communication in medicine (DICOM) Standard is an evolving standard and it is maintained in accordance with the Procedures of the DICOM Standards Committee. Proposals for enhancements are forthcoming from the DICOM Committee member organizations based on input from users of the Standard. These proposals are considered for inclusion in future editions of the Standard. A requirement in updating the Standard is to maintain effective compatibility with previous editions(**NEMA, 2003**).

For example, one of the recent supplements to the DICOM standard is supplement 23 which is an introduction to the structured reporting (SR) classes (**NEMA, 2000**), which are used for transmission and storage of clinical documents. The SR classes fully support both conventional free text reports and structured information, thus enhancing the precision, clarity, and value of clinical documentation. In addition, the SR standard provides the capability to link text and other data to particular images or waveforms and to store the coordinates of findings (**NEMA 2003–Hussein et al, 2004**).

Also, some software tools throughout the radiology community have been extended to incorporate features of a DICOM viewer. For example, the Microsoft power point. Although PowerPoint has become a ubiquitous presentation tool in medical imaging, it does not support the Digital Imaging and Communications in Medicine (DICOM) standard. Users must go through a laborious conversion process that includes guessing the appropriate brightness and contrast to convert 16-bit DICOM images into 8-bit formats. A PowerPoint add-in was developed that incorporates features of a DICOM viewer into a presentation. Users can interactively manipulate large series of 16-bit images in stack mode with scroll, crop, zoom, and window width and level functions, as well as sort through images by location or series. Multiple DICOM image series can be placed on a single slide, and one can interactively scroll through stacks of images during a presentation to demonstrate imaging findings. The problem created by the varying contrast and brightness of different projector systems is overcome by interactively adjusting the image window level during presentations. Bone and lung window views can be shown without having to create separate images. Combining DICOM images into stacks as part of a PowerPoint presentation can result in a more effective and higher-quality presentation of medical images (**Haider, 2003–Corl et al 2002**).

Aim of work

The aim of this work is to provide an overview of the expansions of DICOM standard's scope, either the new supplements added to the DICOM standard or corrections made to maintain the standard. Also media (as DVD-R and E-mail attachments) or objects (as multi-frame MR or multi-frame CT) added to the DICOM standard. Also to explain how Advances in DICOM standard development and employment have paved the way to full-field digital community.

▷ *INTRODUCTION*

For more than 25 years the vision of the all-digital radiology department has been a beacon guiding radiologists, computer scientists, and industrial developers in creating the equipment and the standards necessary to achieve this goal. Many all-digital or mostly digital radiology departments exist today (Siegel EL et al, 2003) and serve as testimonies of the many

breakthroughs that have been required to meld historically disparate imaging and information systems together under
