

Nutritional Status of Children with Congenital Heart Disease: before and after cardiac surgery and Therapeutic Catheterization.

Thesis

**Submitted for Partial Fulfillment of Master Degree
in Pediatric medicine**

By

Yosra Yosef Mohy-Eldin Ramadan

Supervised by

Prof. Shereen Abd-Elghaffar Taha

*Professor of Pediatric
Faculty of Medicine – Cairo University*

Prof. Aya Mohamed Fattouh

*Assist. Professor of Pediatric
Faculty of Medicine - Cairo University*

Prof. Reem Ibrahim Esmail

*Assist. Professor of Pediatric
Faculty of Medicine - Cairo University*

**Facutly of Medicine - Cairo University
2016**

Acknowledgment

*First and foremost, I feel always indebted to **ALLAH**, the Most Kind and Most Merciful.*

*I'd like to express my respectful thanks and profound gratitude to **Prof. Shereen Abd-Elghaffar**, Professor of Pediatric, for her keen guidance, kind supervision, valuable advice and continuous encouragement, which made possible the completion of this work.*

*I am also delighted to express my deepest gratitude and thanks to **Prof. Aya Fattouh**, Assist.Professor of Pediatric, for her kind care, continuous supervision, valuable instructions, constant help and great assistance throughout this work.*

*I am deeply thankful to **Prof. Reem Ibrahim**, Assist.professor of Pediatric, for her great help, active participation and guidance.*

I would like to express my hearty thanks to all my family especially my mother, father and husband for their support till this work was completed.

Last but not least my sincere thanks and appreciation to all patients participated in this study.

Yosra Yosef Mohy-Eldin Ramadan

Abstract

Background: Congenital heart disease (CHD) accounts for more infant deaths than all other congenital defects put together. It is a popular view that children with congenital heart disease are often small and undernourished. Infants with CHD are prone to malnutrition for several reasons including decreased energy intake, increased energy requirements, or both. The severity of malnutrition can range from mild under-nutrition to failure to thrive. This can have a notable effect on the outcome of surgery, increasing morbidity and mortality. Different types of cardiac malformations can affect nutrition and growth to varying degrees. The maintenance of nutritional homeostasis is fundamental to normal health.

Objective: Assessment of nutritional status and growth centiles of pediatric patients with CHD at Cairo University Hospital before and after cardiac surgery or interventional cardiac catheterization.

Patients and methods: 40 children fulfilling the inclusion criteria will be subjected to: Full history, general examination, thorough cardiac examination, anthropometric measurements, for assessment of growth pattern, biochemical data and related tests, echocardiography. The anthropometry, biochemical data and related tests will be obtained one day before and three months after intervention either surgical or transcatheter.

Inclusion criteria: Pediatric age group from 1 month till 12 years old with all the following:

- (1) Confirmed medical diagnosis of CHD documented by echocardiography.
- (2) Candidate for palliative or corrective heart surgery or interventional catheterization.

Results: In the current study, 40 patients with CHD (27 acyanotic and 13 cyanotic) with their age ranged from 1 month to 12 years, 21 female and 19 male, underwent corrective procedure (therapeutic catheterization and surgery). Our patients showed marked decrease of weight (mean 9.08 ± 6.84), height (mean 76.45 ± 21.15) and BMI (mean 13.41 ± 2.52) before correction of malformations. Significant (p value < 0.001) early somatic catch up growth in the following anthropometric measurements; weight, height and BMI was documented. There was severe somatic growth deceleration below 10th percentile it was more pronounced in the cyanotic group of patients, 50% and 86% of them were below the 10th percentile for Wt. and Ht. respectively.

Conclusion: We concluded that Infants with CHD are prone to malnutrition, thorough nutritional assessment by anthropometric measures is important for appropriate nutrition care of the pediatric CHD patient.

Key words: Anthropometric measures, congenital heart disease, cardiac therapeutic procedures.

RR: Respiratory rate
Sao₂: Oxygen saturation
SDS: Standard deviation score
SNS: Sympathetic nervous system
SRIF: Somatostatin release inhibiting factor
T₃: Triiodothyronine
T₄: thyroxine
TAPVR: Total anomaly pulmonary venous return
TGA: Transposition of great arteries
TNF: Tumor necrozing factor
TOF: Teratology of fallot
TRH: Thyroid releasing hormone
TSH: Thyroid stimulating hormone
VSD: Ventricular septal defect
Wt: weight
Yr: year

Introduction

Congenital heart diseases (CHD) consist of defects of the cardiac architecture which interfere with the venous drainage, septation of the cardiac segments and their sequences and regular function of the valve apparatuses. In normal heart, segments are disposed in such a way to allow deoxygenated venous blood to go to the lungs through the pulmonary artery and the oxygenated venous blood to go to the systemic organs through the aorta without mixing. Small and great circulations are in sequence, with no communication to each other (*Thiene and Frescura, 2010*).

Children with congenital heart diseases are exposed to the potential risks of hypoxia, acidosis and hypotension (*Gaynor et al., 2007*).

Children with congenital heart disease (CHD) are at increased risk for poor growth, several factors may play a role including feeding difficulties, increased caloric requirements, and the effects of cardiac lesions on growth regulation (*Knirsch et al., 2013*).

Growth retardation is a hallmark of chronic illnesses (*Gaynor et al., 2007*).

Growth impairment is frequently observed in infants with congenital heart diseases (CHDs). The growth chart should reflect height and weight in terms of absolute values and also in percentiles. Accurate plotting and following of the

growth curve are essential parts of the initial and follow-up evaluations of a child with significant heart problems (*Gaynor et al., 2007*).

Different patterns of growth impairment are seen in different types of CHD. Cyanotic patients have disturbances in both height and weight. Acyanotic patients, particularly those with a large left-to-right shunt, tend to have more problems with weight gain than with linear growth (*Park, 2008*).

Poor growth in a child with a mild cardiac anomaly or failure of catch-up weight gain after repair of the defect may indicate failure to recognize certain syndromes or may be due to the underlying genetic predisposition (*Park, 2008*).

Aim of the work

Assessment of nutritional status and growth of pediatric patients with congenital heart disease before and after cardiac surgery or interventional cardiac catheterization.
