Ain Shams University

2015

Acknowledgement

First of all, thanks to Allah who guided me through this work.

*I would like to express my deepest gratitude and most sincere thanks to **Prof. Dr. Mohamed Salah Gabal** Professor of community, environment and occupational medicine, faculty of medicine, Ain Shams university for his patience, time, valuable help and advice in every step of this work.*

*It is pleasurable to express my deepest thanks to **Dr. Hasnaa Abdel-Aal Abousaif** Assistant Professor of community, environment and occupational medicine, faculty of medicine, Ain Shams University for her great and continuous efforts, support, and precious advice during the supervision of this work.*

*I would like to thank **Dr. Waleed Salah-Eldin** Lecturer of community, environment and occupational medicine, faculty of medicine, Ain Shams University for his continuous efforts during the work.*

I would like to thank my parents, my lovely husband.

Finally, I want to thank all staff members of Public Health and Community Medicine Department of Faculty of Medicine Ain Shams University for their help and support during this work. Also, many

Abstract

Back ground: Hypertensive disorders of pregnancy are a major cause of maternal and fetal mortality and morbidity, and affect approximately 8% of all pregnancies.

Objective: To identity frequency of hypertension among pregnant women attending (MCH) centers in Belbeis city and to identify probable factors associated with hypertension.

Study design: A cross–sectional study included 554 pregnant women after 20 weeks of gestation enrolled from 2 rural primary heath care centers in Belbeis City (Sharkia governorate) during the period from the first of September 2014, to end of April 2015.

Result: The study revealed that, the percentage of hypertension among pregnant women was 4.5% and there were no cases of preeclampsia. The significant risk factors predisposing development of hypertension during pregnancy were age of mother, smoking, family size, weight of mother, presence of diabetes mellitus, renal diseases and history of hypertension in previous pregnancy. By logistic regression only age of mother was independent predictor of hypertension in pregnant mother.

Recommendation: The health care physicians in the (MCH) Centers should increase their efforts to provide the high risk pregnant women as early possible with proper antenatal care and management of hypertension during pregnancy.

Key words: hypertension, pregnancy

Introduction

Introduction

Gestational hypertension or pregnancy induced hypertension (PIH) is the development of new hypertension in pregnant women after 20 weeks gestation without the presence of protein in the urine or other signs of preeclampsia. Hypertension is defined as greater than 140/90 mm Hg (**Lo et al, 2013**).

Pre-eclampsia (PE) is a disorder of pregnancy characterized by high blood pressure and a large amount of protein in the urine (>300 mg of protein in a 24-hour urine sample) with additional medical signs and symptoms. HELLP syndrome is a type of preeclampsia. It is a combination of three medical conditions: Hemolytic anemia, Elevated Liver Enzymes and Low Platelet count (**Eiland et al, 2012**). The disorder usually occurs in the third trimester of pregnancy and gets worse over time (**Al-Jameil et al, 2014**) and (**Report of the American college, 2013**).

Eclampsia is considered when tonic-clonic seizures appear in a pregnant woman with high blood pressure and proteinuria. Pre-eclampsia and eclampsia are sometimes treated as components of a common syndrome (**Dorland's Medical Dictionary for Health Consumers**).

The word eclampsia is from the Greek term for lightning. The first known description of the condition was by Hippocrates in the 5th century BCE (**Mohler, 2006**).

Hypertensive disorders in pregnancy resulted in 29.000 deaths worldwide on 2013 down from 37.000 deaths in 1990 (**GBD, 2015**).

They are one of the three major causes of death in pregnancy (16%) along with postpartum bleeding (13%) and puerperal infections (2%) (**Hoffman et al, 2014**). In Egypt, maternal mortality ratio is reported to be 45 per 100000 live births according to (**WHO, 2013**).

About (10%) of pregnancies globally are complicated by hypertensive diseases (**WHO recommendations, 2011**). In United States hypertensive disease of pregnancy affect about (8%) to 13% of pregnancies and Rates have increased in the developing world (**Lo et al, 2013**).

In a study conducted to estimate the prevalence of hypertensive diseases of pregnancy in Egypt (4.2%) had pregnancy induced hypertension (3.8 %) had preeclampsia and eclampsia was (0.3%) (**Eldeeb et al, 2015**).

Gestational hypertension or PIH is associated with worse outcomes (**Arulkumaran & Lightstone, 2013**). Women who have had preeclampsia are at increased risk of heart disease later in life (**Steeegers et al, 2010**).

Complications of preeclampsia can affect both the mother and the fetus. Acutely, preeclampsia can be complicated by eclampsia, the development of HELLP syndrome (hemolysis, elevated liver enzymes , low platelet count), hemorrhagic or ischemic stroke, liver damage and dysfunction, acute kidney injury, and acute respiratory distress syndrome (ARDS) (**Arulkumaran & LightStone, 2013**). An individual with preeclampsia is at increased risk for recurrence of preeclampsia in subsequent pregnancies. There is also an increased risk for cardiovascular complications, including hypertension and ischemic heart disease, and kidney disease (**Mustafa et al, 2012**).

Preeclampsia is also associated with increased frequency of Caesarian section, preterm delivery, and placental abruption. Furthermore, an elevation in blood pressure can occur in some individuals in the first week postpartum attributable to volume expansion and fluid mobilization (**Mustafa et al, 2012**).

Fetal complications include fetal growth restriction and a potentially fetal or perinatal death (**Mustafa et al, 2012**).

Although much research into mechanism of preeclampsia has taken place, its exact pathogenesis remains uncertain. Preeclampsia is thought to result from an abnormal placenta (**Al-Jameil et al, 2014**).

Known risk factors for preeclampsia include null parity (never given birth), Diabetes mellitus (DM), kidney disease, chronic hypertension, prior history of preeclampsia, family history of advanced maternal age (>35 years), obesity, anti-phospholipid antibody syndrome, multiple gestation, having donated a kidney and having sub-clinical hypothyroidism or thyroid antibodies (**Garg et al, 2014**).

This study was conducted to estimate frequency of hypertension among pregnant women attending rural health care centers in Belbeis city and to identify probable factors associated with hypertension. Knowing prevalence of hypertension among a sample of pregnant women in rural area may help strengthen the role family physicians and health care centers in early detection and improvement of outcome in pregnancy associated hypertension.

Aim of the work and objectives

Goal of the study

The goal of this study is to improve the health status of the pregnant women and their infants and reduce morbidity and mortality rates of them.

Objectives

- 1- To identify frequency of hypertension among the pregnant women attending the maternal and child health care (MCH) centers in Belbeis City more than 20 weeks.
- 2- To identify probable factors associated with hypertension in pregnancy.

Review of literature

Definition

Definition of hypertension:

Hypertension, also known as high or raised blood pressure, is a condition in which the blood vessels have persistently raised pressure. Blood is carried from the heart to all parts of the body in the vessels. Each time the heart beats, it pumps blood into the vessels. Blood pressure is created by the force of blood pushing against the walls of blood vessels (arteries) as it is pumped by the heart. The higher the pressure the harder the heart has to pump **(WHO, 2013)**.

Normal adult blood pressure is defined as a blood pressure of 120 mm Hg¹ when the heart beats (systolic) and a d pressure of 80 mm Hg when the heart relaxes (diastolic). When systolic blood pressure is equal to or above 140 mm Hg and/or a diastolic blood pressure equal to or above 90 mm Hg the blood pressure is considered to be raised or high **(WHO, 2013)**.

Definition of preeclampsia:

Hypertensive disorders of pregnancy (HDP) constitute the commonest medical disorder diagnosed by obstetricians representing 7% to 10% of all pregnancies **(Magee et al, 2009)**.

Preeclampsia is a multiorgan disease process of unknown etiology characterized by the development of hypertension and proteinuria after 20 weeks of gestation **(davison et al, 2004)**.

The frequency of preeclampsia varies between 2% and 7% in healthy nulliparous women **(vatten et al, 2004)**.

Preeclmpsia is systolic blood pressure more than 140mmhg or the diastolic blood pressure more than 90mmhg that begins after 20 weeks of gestation and is accompanied by proteinuria **(Davison et al, 2004)**.
