DEFORMATIONS OF GENERALIZED HYPERRULED SURFACES AND THEIR STABILITY IN THE EUCLIDEAN SPACE E^{n+1}

A THESIS

**Submitted to the Faculty of Science , Assiut University
In Partial Fulfillment for The Degree of
Doctor of Philosophy
(Mathematics)**

By

**Hamdy Nour El-Din Abd-Ellah
M. Sc., in Mathematics (1991)**

Supervised By

Dr. Mohamed A. Soliman
Professor of Mathematics
faculty of Science , Assiut University

Dr. Nassar H. Abdel-All
Professor of Mathematics
faculty of Science , Assiut University

Dr. Otto Roeschel
Professor and head of Institute
for Geometry, TU, Graz, Austria

Dr. Rashad A. Abd El-Baky
Lecturer of Mathematics
faculty of Science , Assiut University

**Mathematics Department, Faculty of Science,
Assiut University, EGYPT.**

1999

"بسم الله الرحمن الرحيم"

ACKNOWLEDGEMENTS

ACKNOWLEDGMENTS

In the name of **ALLAH**, the Beneficent, the Merciful. All praise is due to **ALLAH**, the Lord of the Worlds. I do indeed thank **ALLAH** Almighty Who guided and aided me to bring to light this thesis.

I would like to express my thanks and gratefulness to the Egyptian Government for offering this fellowship through the channel system program (9.2) and to the Austrian Government for facilitating my stay in Austria during my work on this thesis.

It is a pleasure to express my deep gratitude to **Prof. M. I. Mahmoud**, Head of Mathematics Department, Assiut University, for his fatherly kindness.

I am also grateful to **Prof. M. A. Soliman**, for his supervision, helpful, advices, continuous encouragement and valuable discussion.

My sincere thanks to **Prof. N. H. Abdel-All**, for his direct supervision of the work, planning of the study, efforts in revising and reading the thesis and the many precious facilities he generously offered during the development of this work.

Thanks are due to **Prof. H. Vogler**, Dean of the Faculty of Science, Technische Universität Graz, who shared in supervising, for his unfailing supervision, supporting and continuous help.

This work has been realised at the above mentioned University, Institut für Geometrie directed by **Prof. O. Röschel**. To him and to all members of the Institut, I express my deep gratitude for their great help and encouragement throughout my work.

I express my deep gratitude to **Dr. R. A. Abdel-Baky**, Lecturer of Mathematics, Faculty of Science, Assiut University, for his kind advices.

I also wish to express my deepest gratitude to the staff members, my colleagues in Mathematics Department and to every person who has generously contributed their time during the preparation of this thesis.

Hamdy Nour El-Din Abd-Ellah

PREFACE	i
Chapter 1 : GEOMETRIC PRELIMINARIES	
1.1 Characteristic properties of curves in E^{n+1}	1
1.1.1 The Frenet frame and its motion	3
1.2 Submanifolds	5
1.3 Ruled surfaces in E^n	10
1.4 Examples of ruled surfaces	15
1.4.1 Cylindrical surfaces	16
1.4.2 Conical surfaces	16
1.4.2 Tangential surfaces	16
Chapter 2 : GEOMETRIC INVARIANTS ON AN m-DIMENSIONAL RULED MANIFOLD	
2.1 Introduction	23
2.2 Algebraic invariants	24
2.3 Curvatures of higher orders	28
2.4 The normal curvature	31
2.5 Application in E^4	33
Chapter 3 : STABILITY OF CLOSED HYPERRULED SURFACES	
3.1 Introduction	37
3.2 General hyperruled surface in E^{n+1}	38
3.3 The variation of the fundamental quantities and the curvatures	42
3.4 Special hyperruled surface in E^{n+1}	53
3.5 The variation of the quantities g^{ij} and the curvatures on the special ruled Surface M	55
3.6 Applications in E^3 and E^4	57
3.7 Effect of the normal variation on the ruled surfaces	66

Chapter 4 : STABILITY OF DEFORMED OSCULATING HYPERRULED SURFACES

4.1 The fundamental quantities and the curvatures	74
4.2 The variation of the fundamental quantities and the curvatures	77
4.3 The variation of the curvatures for the base curve and the Frenet frame	81
4.4 Stability condition for the deformed osculating hyperruled surface	83

Chapter 5 : STABILITY OF DEFORMED NORMAL HYPERRULED SURFACES

5.1 The fundamental quantities and the curvatures	89
5.2 The variation of the fundamental quantities and the curvatures	92
5.3 The variation of the curvatures for the base curve and the Frenet frame	96
5.4 Stability condition for the deformed normal hyperruled Surface	97

ARABIC SUMMARY

PREFACE

PREFACE

One of the problems of differential geometry is the investigation of manifolds whose generating element is a line in the space being considered.

At the end of the 19th century and in the first half of the 20th century the **differential geometry of families of lines** (the geometry of manifolds of figures) was developed mainly within classical geometry; here were considered families of elementary lines.

The differential geometry of line manifolds (ruled surfaces, line congruences and line complexes) of a three-dimensional space is one of the important branches of differential geometry since it is directly connected with the foundation of this science which is the theory of surfaces. It has direct applications to various applied sciences as hydrodynamics, geometrical optics and field theory. Also it has many applications which are treated in many different branches, for instance, classical, local, global, algebraic and Kinematic study view. This topic was studied by several authors on different types of spaces such as, Euclidean, Elliptic, Hyperbolic, isotropic, flaggen, quasihyperbolic, projective spaces, etc. During this time many general and special results have been obtained on the basis of which there have arisen a number of theories generalizing the simplest three-dimensional constructions and extending then to multidimensional spaces.

The rise of new differential-geometric methods permits us each time to state previously obtained results more simply and concisely, to solve some problems which did not yield to older methods, and to pose new problems whose analyses in their own turn stimulate the appearance of new methods. The application of tensor methods in differential line geometry, connected with the idea of "translation" i.e., the mapping of a set of straight lines of a three-dimensional space onto some point space.

One of the most interesting and profound aspects of classical **differential geometry** is its interplay with the **calculus of variations**. This phenomenon has its roots in the very origins of the subject, such as, for instance, in the theory of minimal surfaces. More recently, the variational principles which give rise to the field equations of the general theory of relativity have suggested the systematic investigation of a seemingly new type of variational problem. In the case of the earlier applications one is, at least implicitly, concerned with a multiple integral in the calculus of variations whose Lagrangian depends on the projection factors of some subspace, these projection factors being obtained by differentiation of the functions which appear in the parametric equations by means of which the subspace is represented; the corresponding Euler-Lagrange equations are

supposed to yield appropriate functions of this kind. The variational problems of the second type referred to above are defined by Lagrangians whose arguments are the components of the metric tensor of a manifold, together with the first and second derivatives of these components, and the resulting Euler-Lagrange equations give rise to the required metric.

Also, the most important geometric variational integrals are given by area (or volume), energy, and curvature integrals. Critical points of area integrals are minimal surfaces and their higherdimensional generalizations, critical points of energy integrals are called harmonic maps, and curvature integrals usually select special metrics or connections. In any case, the basic idea is to select a geometrically most natural representative from a general class of objects (submanifolds, mappings, metrics, etc.) via a variational procedure. Often, one can deduce special properties of such an object from the fact that it is a minimum or a critical point of a variational problem, and one can then in turn use this information to obtain information about the whole geometric class. The area functional and its critical points, the minimal surfaces, were already intensively studied in the last century. While many interesting examples were found and many geometric properties of minimal surfaces were discovered during that period.

In fact, the main differential geometric ideas of the calculus of variation occur over and over again and are continually being invented and rediscovered in a vast array of classical and modern differential geometry.

Here, we give a brief account of the history of the results related to the problems in the thesis which have been obtained previously as follows:

In 1973, Chen [17]; generalized the formulas concerning the stability of surfaces which are introduced by **Pinl and Trapp [49] and Thomsen [62].**

In 1978, Chariar [21]; determined ruled Wiengarten surfaces and found that the line of striction of the generators must be a right circular helix, circle included, or a straight line and the parameter of distribution must be constant. He also, obtained the functional relation between the mean and Gaussian curvatures.

In 1978, Thas [61]; gave some results of the Lipschitz-Killing curvature and the mean curvature vector H of 2-dimensional ruled surfaces in E^n . The ruled surfaces with minimal Lipschitz-Killing curvature in the direction of H are studied. The scalar normal curvature and the minimal index are also investigated.
