
Bronchoscopic Lung Volume Reduction by Histoacryl

Thesis

Submitted for Partial fulfillment of MD Degree in Chest Diseases

Presented by
Hatem Mohammed Shehata

M.B.B.Ch., M.Sc. in chest diseases
Faculty of Medicine
Ain Shams University

Under Supervision of

Professor. Mona Mansour Ahmed

Professor of Chest Diseases
Faculty of Medicine
Ain Shams University

Prof. Ayman Abd Al-Hameed Farghaly

Consultant of Pulmonary Diseases
Military Medical Academy

Professor .Khaled Mohamed Wagih

Professor of Chest Diseases
Faculty of Medicine
Ain Shams University

Dr. Ashraf Abbas ElMaraghy

Assistant Professor of Chest Diseases
Faculty of Medicine
Ain Shams University

Faculty of Medicine
Ain Shams University

2016

ACKNOWLEDGEMENT

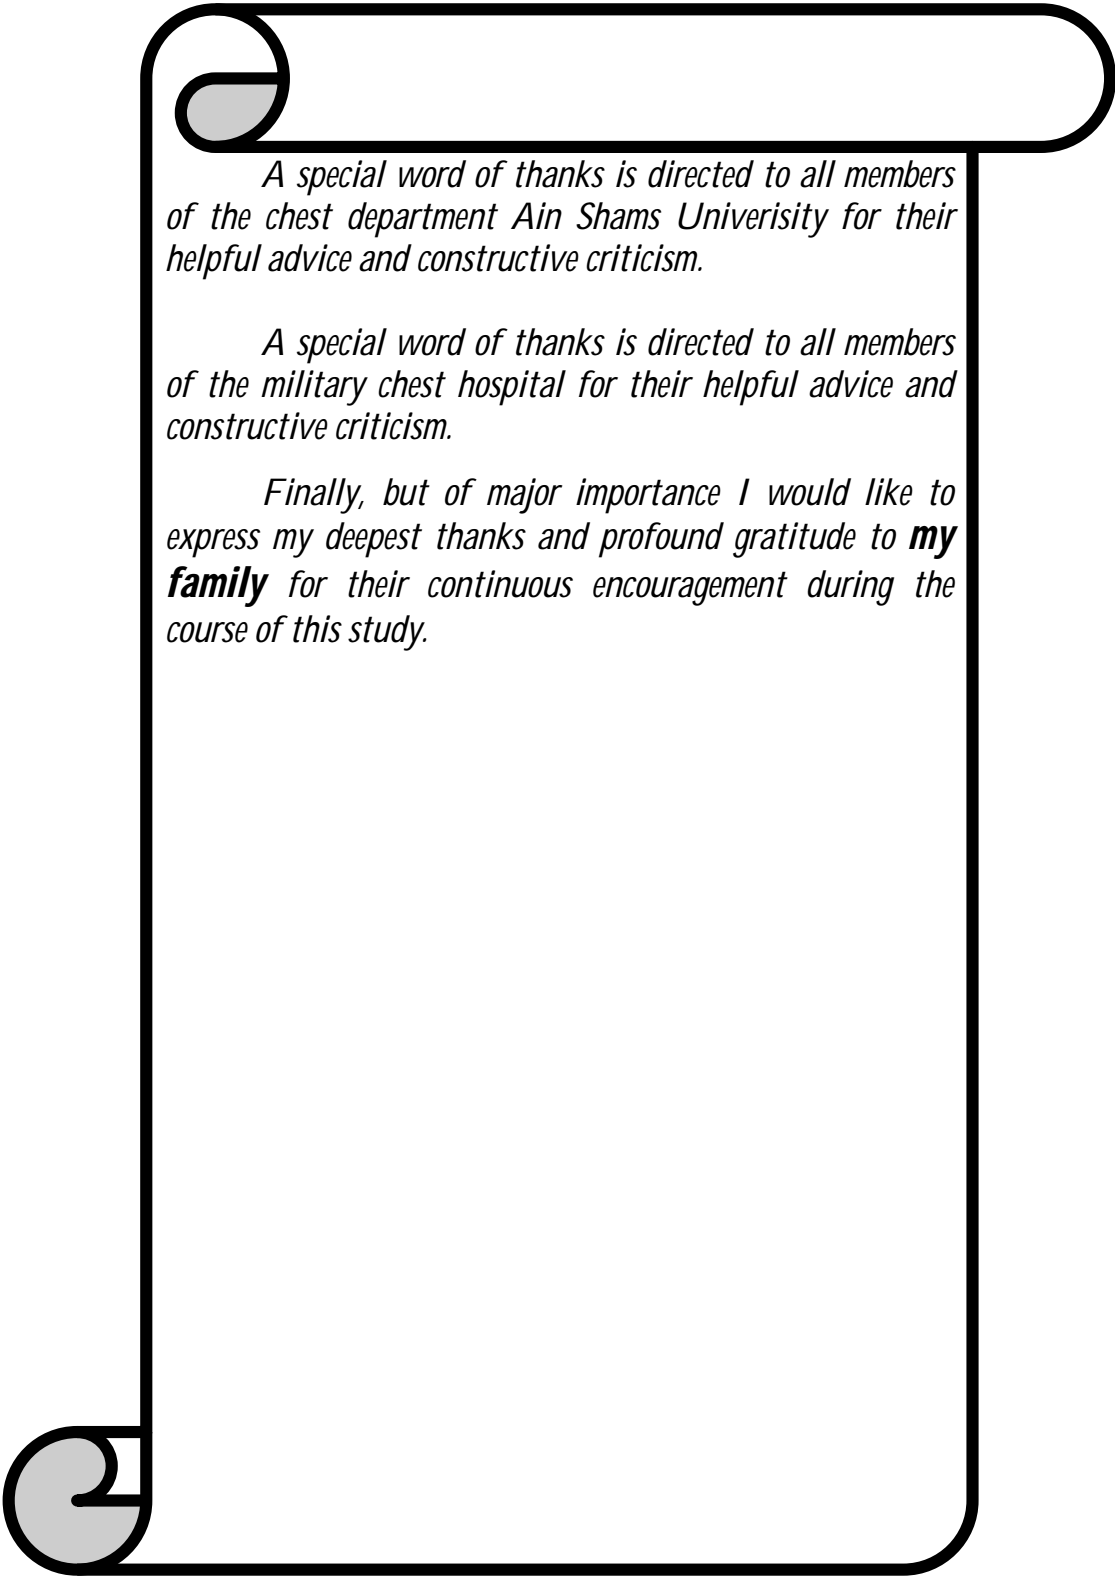

Thanks first and last to Allah as we owe him for his great care, support and guidance in every step in our life.

*It really gives me unlimited pleasure and honor to express my sincere heartfelt gratitude of **Prof. Mona Mansour Ahmed** Professor of Chest Diseases Faculty of Medicine Ain Shams University who has contributed in this work with valuable assistance and in many different ways. I would like to thank her for devoting much of his time to helpful comments and also for her effort throughout this work and kind supervision.*

*It gives me pleasure to express my great indebtedness and appreciation to **prof. Ayman Abd Al-Hameed Farghaly** Consultant of Pulmonary Diseases-Military Medical Academy for his kind supervision, unrelenting support, continuous encouragement, valuable scientific guidance, unlimited help and indispensable advice.*

*It gives me pleasure to express my great indebtedness and appreciation to **Professor. Khaled Wagih** Professor of Chest Diseases ,Faculty of Medicine, Ain Shams University for his valuable and scientific evaluation through the period of my study from the start until the end.*

***& Dr. Ashraf Abbas ElMaraghy** Assistant Professor of Chest Diseases ,Faculty of Medicine, Ain Shams University for his cooperation in collecting the data and unlimited help and indispensable advice.*

A special word of thanks is directed to all members of the chest department Ain Shams Univerisity for their helpful advice and constructive criticism.

A special word of thanks is directed to all members of the military chest hospital for their helpful advice and constructive criticism.

*Finally, but of major importance I would like to express my deepest thanks and profound gratitude to **my family** for their continuous encouragement during the course of this study.*

Introduction

Emphysema is defined pathologically as the presence of permanent enlargement of the airspaces distal to the terminal bronchioles, accompanied by destruction of their walls without obvious fibrosis. Emphysema, or destruction of the gas exchanging surfaces of the lung (alveoli), is a pathological term that is often (but incorrectly) used clinically and describes only one of several structural abnormalities present in patients with COPD (*Hashimoto et al, 2014*).

Emphysema is commonly associated with bullae which are large non-ventilated air-containing intrapulmonary spaces of their walls formed by compressed and attenuated lung tissue. Bullae impart mechanical impediment to the ventilation of adjacent lung parenchyma, increase the residual volume (RV) and RV/total lung capacity ratio and also impair the function of the inspiratory muscles especially the diaphragm. These effects alone may cause symptoms even without the further complications of rupture, infection, etc... (*Krishnamohan et al, 2014*).

Some studies have indicated that lung volume reduction surgery (LVRS) ameliorates dyspnea, increases exercise capacity, improves lung function, enhances health-related quality-of-life measures, and reduces mortality in selected patients with advanced emphysematous bullae. Although beneficial to many emphysema patients, LVRS is associated with an operative mortality rate of 4 to 7%, a morbidity rate of 30 to 50%, and an average hospital stay of 10 to 14 days (*Zahid et al, 2011*).

The development of less invasive and less morbid approaches to lung volume reduction would represent a substantial advance in the treatment of emphysematous bullae. Several bronchoscopic procedures designed to reduce lung volume in patients with emphysema are under development. These include one-way valves, or bronchial occlusive devices to collapse emphysematous regions of lung and bronchial fenestration with bypass stents to improve expiratory flow (*Murphy et al, 2014*).

Shah and Herth (2014) reported that bronchoscopic injection of autologous blood in emphysematous bulla will decrease the bulla in size and improve dyspnea.

Moreover, *Hartman et al, 2014* proved that biological lung volume reduction can be safe and produce benefits in appropriately selected patients with advanced heterogeneous emphysema.

Aim of the work

The aim of this work is to evaluate the safety and efficacy of bronchoscopic lung volume reduction using adhesive material (histoacryl blue) in patients with emphysema and emphysematous bullae.

Review of LiteRatuRe

Chapter (1)

(Emphysema)

The word emphysema is derived from Greek and means “to blow into,” hence “air containing” or “inflated”. Although “voluminous lungs” and lungs “turgid particularly from air” were described respectively by ***Bonet in 1679 and Morgagni in 1769*** the first description of enlarged airspaces in emphysema in the human, together with illustrations, was furnished by ***Matthew Baillie in 1807*** who not only clearly recognized and illustrated emphysema, but also pointed out its essentially destructive character (***Vestbo J., 2013***).

Laennec, 1821 recognized that air trapping and increased collateral ventilation were features of emphysematous lungs, and that the peripheral airways were the primary site of obstruction in emphysema. Furthermore, he noted that air spaces enlarged with increasing age, and he distinguished these changes from emphysema (***Valipour A et al., 2014***).

Assessment of COPD

Determine the severity of the disease, its impact on the patient’s health status and the risk of future events (for example exacerbations) to guide therapy. Consider the following aspects of the disease separately:

- current level of patient’s symptoms
- severity of the spirometric abnormality
- frequency of exacerbations
- presence of comorbidities.

COPD Assessment Test (CAT): An 8-item measure of health status impairment in COPD .

Breathlessness Measurement using the Modified British Medical Research Council (mMRC) Questionnaire: relates well to other measures of health status and predicts future mortality risk.(**GOLD ,2013**)

Table (1): Modified Medical Research Council Questionnaire for Assessing the Severity of Breathlessness

**PLEASE TICK IN THE BOX THAT APPLIES TO YOU
(ONE BOX ONLY)**

- mMRC Grade 0. I only get breathless with strenuous exercise. ☐
- mMRC Grade 1. I get short of breath when hurrying on the level or walking up a slight hill. ☐
- mMRC Grade 2. I walk slower than people of the same age on the level because of breathlessness, or I have to stop for breath when walking on my own pace on the level. ☐
- mMRC Grade 3. I stop for breath after walking about 100 meters or after a few minutes on the level. ☐
- mMRC Grade 4. I am too breathless to leave the house or I am breathless when dressing or undressing. ☐

**Table (2): Classification of Severity of Airflow Limitation in COPD
(Based on Post-Bronchodilator FEV₁)**

In patients with FEV ₁ /FVC < 0.70:	
Mild GOLD 1:	FEV ₁ ≥ 80% predicted
Moderate GOLD 2:	50% ≤ FEV ₁ < 80% predicted
Severe GOLD 3:	30% ≤ FEV ₁ < 50% predicted
Very Severe GOLD 4:	FEV ₁ < 30% predicted

(GOLD, 2013)

Assessment of COPD

- ✓ Assess symptoms
- ✓ Assess degree of airflow limitation using spirometry
- ✓ Assess risk of exacerbations

Use history of exacerbations and spirometry.

Two exacerbations or more within the last year
or an FEV₁ < 50 % of predicted value are
indicators of high risk

Combined Assessment of COPD

- Assess symptoms
- Assess degree of airflow limitation using spirometry
- Assess risk of exacerbations

*Combine these assessments for the purpose of improving
management of COPD (GOLD, 2013).*

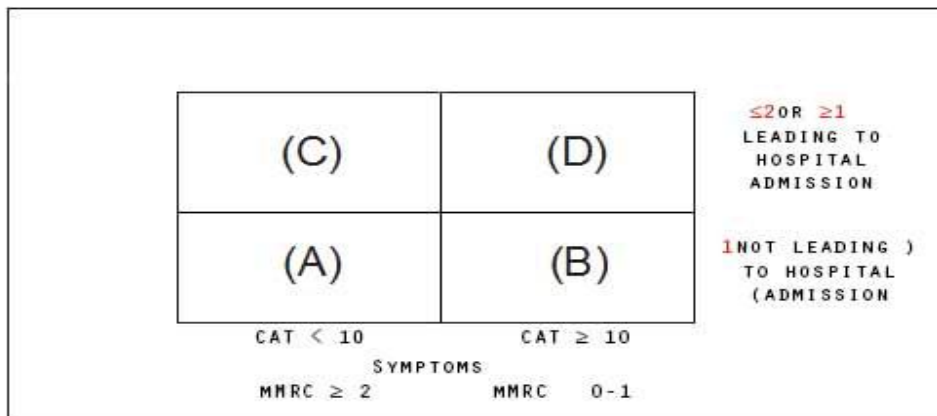

Figure (1): *Assessment Using Symptoms, Breathlessness, Spirometric Classification and Risk of Exacerbations (GOLD, 2013)*

Pathogenesis

Anatomy of respiratory system:

The bronchioles or bronchioli are the passageways by which air passes through the nose or mouth to the alveoli (air sacs) of the lungs, in which branches no longer contain cartilage or glands in their submucosa. They are branches of the bronchi, and are part of the conducting zone of the respiratory system. The bronchioles divide further into smaller terminal bronchioles which are still in the conducting zone and these then divide into the smaller respiratory bronchioles which mark the beginning of the respiratory region. (*Merck., 1997*).

Structure:

A pulmonary lobule is the portion of the lung ventilated by one bronchiole. Bronchioles are approximately 1mm or less in diameter and their walls consist of ciliated cuboidal epithelium and a layer of smooth muscle. Bronchioles divide into even smaller bronchioles, called terminal, which are 0.5mm or less in diameter. Terminal bronchioles in turn divide into smaller respiratory bronchioles which divide into alveolar ducts. Terminal bronchioles mark the end of
