List of Tables

<i>Tab. No.</i>	<i>Details</i>	<i>Page</i>
1-1	Coagulation Factors & Their Functions	15
2-1	Clinical situation of main established antiplatelet agents based on systemic review	29
3-1	Congenital and Acquired bleeding disorders	77
3-2	Traumatic coagulopathy	99
4-1	Pharmacologic data on major anticoagulants	123
4-2	Reversal of Warfarin-Induced Anticoagulation	127
4-3	Conversion of INR Levels to Percentage for Reversal With PCC or Plasma	128
4-4	Approximate Dose of rFVIIa Required to Reach INR 1.5	129
4-5	International Society of Thrombosis and Hemostasis Disseminated Intravascular Coagulation (DIC) Scoring System	132

List of abbreviations

<i>DDAVP</i>	1-desamino-8-D-arginine vasopressin
<i>ACT</i>	Activated clotting time
<i>APTT</i>	Activated partial thromboplastin time
<i>APC</i>	Activated protein C
<i>ACoTS</i>	Acute Coagulopathy of Trauma–Shock
<i>ACS</i>	Acute Coronary Syndrome
<i>APL</i>	Acute Promyelocytic Leukemia
<i>ATLS</i>	Acute Trauma Life Support
<i>APSAC</i>	Acylated plasminogen – streptokinase activator complex
<i>ATP</i>	Adenosin Triphosphate
<i>ADP</i>	Adenosine diphosphate
<i>AMP</i>	Adenosine monoiphosphate
<i>AC</i>	Adenylate cyclase
<i>APLAS</i>	Antiphospholipid Antibody Syndrome
<i>AT</i>	Antithrombin
<i>ATIII</i>	Antithrombin III
<i>RGD</i>	ARginine-Glycine-aspartate
<i>ANP</i>	Atrial natriuretic peptides
<i>B.U</i>	Betheda unit
<i>CFT</i>	Clot Firmness Time
<i>CABG</i>	Coronary Artery Bypass Graft
<i>COX-1</i>	Cyclooxygenase-1
<i>COX-2</i>	Cyclooxygenase-2
<i>DS</i>	Danaparoid sodium
<i>DVT</i>	Deep Vein Thrombosis
<i>DCP</i>	Des-gamma-carboxy prothrombin

<i>DTIs</i>	Direct Thrombin inhibitors
<i>DIC</i>	Disseminated Intravascular Coagulation
<i>EAC</i>	Endogenous Acute Coagulopathy
<i>EPCR</i>	Endothelial protein C receptor
<i>EDRF</i>	Endothelial-derived relaxing factor
<i>EGF</i>	Epidermal Growth Factor
<i>EACA</i>	Epsilon-aminocaproic acid
<i>FDPs</i>	Fibrin-Degradation Products
<i>FDA</i>	Food and Drug Administration
<i>FFP</i>	Fresh Frozen Plasma
<i>FEIBA</i>	FVIII Inhibitor Bypassing Activity
<i>GM</i>	Gabexate Mesilate
<i>GPIIb/IIIa</i>	Glycoprotein IIb/IIIa
<i>GAG</i>	Glycosaminoglycan
<i>GMP</i>	Guanosine monophosphate
<i>HELLP</i>	Hemolytic Anemia, Elevated Liver Enzymes and Low Platelet count Syndrome
<i>HUS</i>	Hemolytic Uraemic Syndrome
<i>HIT</i>	Heparin Induced Thrombocytopenia
<i>HUVEC</i>	Human Umbilical Vein Endothelial Cells
<i>IL-1</i>	Interleukin 1
<i>INR</i>	International Normalized Ratio
<i>ISI</i>	International Sensitivity Index
<i>KIU</i>	Kallikrein Inactivator Units
<i>LR</i>	Lactated Ringer's solution
<i>LC</i>	Liver cirrhosis
<i>LMWH</i>	Low-molecular-weight-heparins
<i>MBL</i>	Mannose Binding Lectin

<i>MCF</i>	Maximum clot firmness
<i>MAPK</i>	Mitogen Activated Protein Kinase
<i>MW</i>	Molecular wieght
<i>MI</i>	Myocardial Infarction
<i>SNAC</i>	N-(8-(2-hydroxybenzoyl) amino) caprylate
<i>NM</i>	Nafamstat Mesilate
<i>NAPc2</i>	Nematode Anticoagulant Peptide
<i>NCX</i>	Nitric oxide-releasing aspirin
<i>NSTEMI</i>	Non S-T elevating myocardial infarction
<i>PCI</i>	Percutaneous Coronary Intervention
<i>PAD</i>	Peripheral Arterial Disease
<i>PDE</i>	Phosphodiesterase Enzyme
<i>PLC</i>	phospholipase-C
<i>PAI-1</i>	Plasminogen Activator Inhibitor-1
<i>PVT</i>	Portal Vein Thrombosis
<i>PG-I</i>	Prostaglandin I
<i>PAR-1</i>	Protease Activated Receptor 1
<i>PC</i>	Protein C
<i>PIVKA</i>	Protein in VK absence
<i>PS</i>	Protein S
<i>PCC</i>	Prothrombin complex concentrate
<i>PT</i>	Prothrombin time
<i>PSGL-1</i>	P-selectin glycoprotein ligand 1
<i>PE</i>	Pulmonary Embolism
<i>RCTs</i>	Randomised controlled trials
<i>rFVIIa</i>	Recombinant activated factor VII
<i>RT</i>	Reptilase time
<i>RoTEM</i>	Rotation thrombelastogram analyzer

<i>scuPA</i>	single chain urokinase type plas minogen activator
<i>STEMI</i>	S-T elevating myocardial infarction
<i>SAK</i>	Staphylokinase
<i>SPI</i>	Synthetic or purified protease inhibitors
<i>SAC</i>	Systemic Acquired Coagulopathy
<i>SIRS</i>	Systemic Inflammatory Response Syndrome
<i>TNK-t-P</i>	Tenecteplase
<i>TT</i>	Thrombin Time
<i>TAFI</i>	Thrombin-activatable-fibrinolysis-inhibitor
<i>TAT</i>	Thrombin–Antithrombin
<i>TEG</i>	Thromboelastography
<i>TE</i>	Thromboembolism
<i>TM</i>	Thrombomodulin
<i>TM</i>	Thrombo-moduline
<i>TTP</i>	Thrombotic thrombocytopenic purpura
<i>TXA2</i>	Thromboxane A2
<i>TP</i>	Thromboxane receptor
<i>TF</i>	Tissue Factor
<i>TFPI</i>	Tissue factor pathway inhibitor
<i>tPA</i>	Tissue plasminogen activator
<i>TGFβ</i>	Transforming growth factor β
<i>TIA</i>	Transiant ischemic attack
<i>TNF</i>	Tumour Necrosis Factor
<i>UFH</i>	Unfractionated Heparin
<i>VTE</i>	venous thromboembolism
<i>VK</i>	Vitamin K
<i>VKA</i>	Vitamin K Antagonist
<i>vWF</i>	von Willebrand factor

Introduction

Disorders of hemostasis and thrombosis are frequently encountered in the ICU setting. Understanding the relevance of laboratory findings is essential in providing appropriate therapy. Various blood products and hemostatic agents are available to assist in the control of bleeding, and several different classes of anticoagulants are now available for use. Appropriate use of these agents maximizes therapeutic effect while minimizing complications. Use of fresh frozen plasma, cryoprecipitate, and other hemostatic agents should generally be reserved for those who have active bleeding, those undergoing invasive procedures, and those at high risk for bleeding because of their underlying diagnoses or because of associated hematologic derangements (*Marks PW, 2009*).

Acquired Coagulation disorders in critically ill patients result from basic mechanisms: Vitamin K deficiency, Liver disease, consumption of factors, or inhibition of factor activity or fibrin polymerization. Unlike inherited disorders, acquired coagulation disorders are often characterized by multiple factor deficiencies as well as platelet defects (quantitative and qualitative) (*Bongard et al., 2008*).

Chronic liver diseases are associated with thrombocytopenia and/or thrombocytopathy, decreased synthesis of most coagulation factors and hyperfibrinolysis. Because of the above characteristics chronic liver disease has been identified until recently as the prototype of the acquired hemostasis abnormalities and the causal relationship between abnormal hemostasis tests and the risk of bleeding has become a paradigm (*Tripodi A, 2010*).

Anticoagulant agents are often used for the prevention and treatment of a wide range of cardiovascular diseases. The most frequently used anticoagulants are heparin or its derivatives, vitamin K antagonists (such as warfarin or coumadin) and antiplatelet agents. The most important complication of treatment with anticoagulants is hemorrhage, which may be serious, may cause long-term debilitating disease, or may even be life-threatening. If severe bleeding occurs or if a patient needs to undergo an urgent invasive procedure, such as emergency surgery, it may be necessary to reverse the anticoagulant effect of the various agents. Depending on the clinical situation, i.e., the severity of the bleeding or the urgency and estimated risk of the invasive procedure, this reversal may take place over a few hours, but in some cases immediate reversal is necessary (*Levi M, 2009*).

Disseminated intravascular coagulation (DIC) is generally considered to be characterized by intravascular activation of coagulation with the loss of localization, which mainly occurs in the small veins and arteries due to various causes. The most common underlying diseases in patients with **DIC** are leukemia, infectious diseases, solid cancer, obstetric complications and aortic aneurysms. It may be classified as follows: asymptomatic type, marked bleeding type, and organ failure type. Although treatment of **DIC** is important, adequate treatment differs according to type of **DIC** (*Wada H et al., 2010*).

Abnormal coagulation parameters can be found in 25% of *trauma* patients with major injuries. Furthermore, trauma patients presenting with coagulopathy on admission have worse clinical outcome. Tissue trauma and systemic hypoperfusion appear to be the primary factors responsible for the development of acute traumatic coagulopathy after injury. This coagulopathy can then be exacerbated by subsequent physiologic and physical derangements such as consumption of coagulation factors, haemodilution, hypothermia, acidemia and inflammation, all factors being associated with ongoing haemorrhage and inadequate resuscitation or transfusion therapies (*Ganter M and Pittet J 2010*).

Chapter 1

Physiology of Hemostasis

Hemostasis is a highly adaptive process that control blood fluidity, and rapidly induces hemostatic plug formation after vascular injury, in order to stop or limit bleeding. After an initial triggering event, sequential steps occur, including a complex cascade of clotting factor and platelet activation. Red blood cells, leukocytes and endothelial cells are also involved in the propagation and the regulation of clot formation (*Lasne et al., 2006*).

Moreover, the coagulation system is not only made for forming clots but is also involved in a variety of defense systems against micro-organisms, autoimmune processes, arteriosclerosis, tumour growth and metastasis. The main cellular components of the coagulation system are platelets, endothelial cells, monocytes and erythrocytes, and the main molecular components are the coagulation factors and inhibitors, fibrinolysis factors and inhibitors, adhesive proteins (e.g. von Willebrand factor), intercellular protein, acute-phase proteins, immunoglobulins, calcium ions, phospholipids, prostaglandins, and certain cytokines (*Bombeli and Sphan, 2004*).

Knowledge of the coagulation system continues to evolve from early concepts of zymogen clotting factors and cofactors activating and cofactors activating in sequence through two separate pathways, intrinsic and extrinsic to generate fibrin for clotting, to a more encompassing process that includes the vascular endothelium, blood coagulation, prevention of clotting and fibrinolysis. The fundamental principle that governs the coagulation system is the unremitting drive to balance procoagulant and anticoagulant forces. (*Oliver WC, 2009*).

The term **Hemostasis** means prevention of blood loss, either by the physiological properties of vasoconstriction and coagulation or by surgical means. (*Colman RW, 2006*).

Mechanisms of Hemostasis:

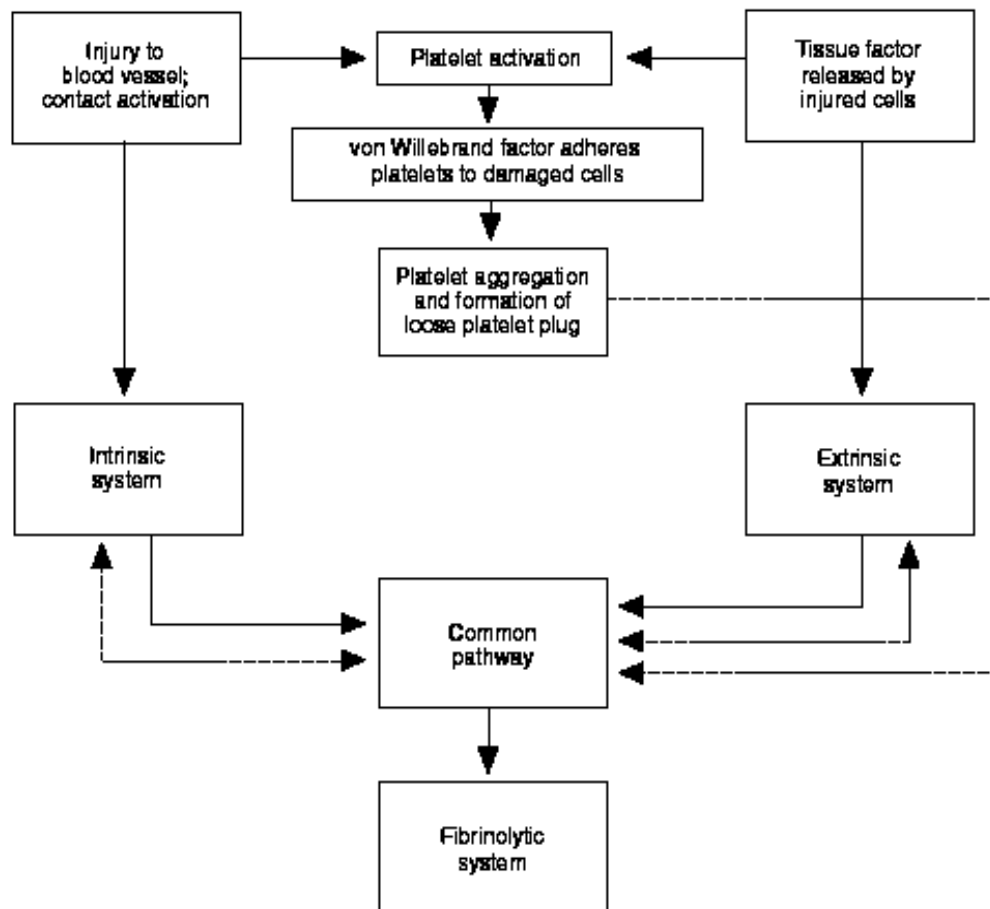

1- Vascular constriction.

2- Formation of a platelet plug.

3- Formation of a blood clot.

4- Eventual growth of fibrous tissue into the blood clot to close the hole in the vessel permanently.

(Guyton and Hall, 2006)

(Figure1-1): The coagulation an overview 2005 American Association of Clinical Chemistry.

1- Vascular constriction:

Immediately after a blood vessel has been cut or ruptured, the trauma to the vessel wall itself causes the smooth muscle in the wall to contract; the contraction results from:

- a) Local myogenic spasm.
- b) Local autacoid factors from the traumatized tissues and blood platelets.
- c) Nervous reflexes are initiated by pain impulses or other sensory impulses that originate from the traumatized vessel or nearby tissues.

The more the severely a vessel is traumatized, the greater the degree of vascular spasm. The spasm can last for many minutes or even hours, during which time the processes of platelet plugging and blood coagulation can take place. (*Guyton and Hall, 2006*)

However, a number of physiological derived compounds appear to induce vasoconstriction of a transient nature at the site of vascular injury. These include participation of endothelin, a very potent vasoconstrictor which is synthesized by endothelial cells, thromboxane A₂ (TXA₂), serotonin and the α -adrenergic system. Thrombin, thromboxane A₂ IL-1, transforming growth factor β (TGF β), angiotensin II and epinephrine promote the expression of the endothelin mRNA, whereas shear stress, atrial natriuretic peptides (ANP) and brain natriuretic peptides negatively modulate its expression. Endothelial-derived relaxing factor (EDRF), an inhibitor of platelet function, inhibits release of endothelin (*Arthur SB, 1998*).
