TO MY PARENTS AND MY PARENTS-IN-LAW

I'm greatly indebted to Prof. Dr. Ramadan Hamed, Professor of Statistics, Dept. of Statistics, Faculty of Economics and Political Science for his valuable and generous assistance. My sincere thanks are also dedicated to him for this constructive guidance and warm encouragement throughout the preparation of this thesis.

Prof. Dr. Kamal Selim, Professor of Statistics, Dept. Of Social-Science Computing, Faculty of Economics and Political Science deserves my deepest gratitude and appreciation for his kind supervision, continuous help and active discussions during the preparation of this thesis.

My deepest gratitude and appreciation and extended also to Prof Dr. Tarek Emira, Professor of Statistics, Chief of Dept. of Statistics, Faculty of Economics and Political Science for his valuable and constructive comments, and to Prof Dr. Maged George for his generous acceptance of discussion of this thesis.

Simulation Study for Cluster Analysis

Abstract

A Monte Carlo simulation study of four clustering methods –Complete linkage , Ward’s method, K-means method and AutoClass Bayesian classification-for determining the best partitioning is conducted on some artificial data sets. The results indicated that the classification obtained by the four clustering methods is affected by increasing the number of clusters in the data sets when error-free data sets are used. All clustering methods perform better than AutoClass Bayesian classification method when number of clusters in data sets is small while the performance of AutoClass Bayesian classification is better than other clustering methods when number of clusters in data sets is large. The results indicated that the classification obtained by the four methods is affected by dimension, noise, and outliers conditions. All clustering methods are affected by outliers. The performance of all clustering methods is decreased with increasing the number of clusters except for AutoClass Bayesian classification, its performance is increased with increasing the number of clusters.

Keywords

- Cluster analysis
- Bayesian classification
- Monte Carlo simulation
- Cluster validity
- Homogeneity and Separation measures

Simulation Study for Cluster Analysis

Summary of the thesis:

Few studies which focus on the comparison of hierarchical and nonhierarchical clustering methods with Bayesian classification are available in the literature. These studies are very limited in the variation of test conditions, such as cluster size and number of clusters present in the data.

For a given data set, each clustering method may identify groups whose member objects and/or number of clusters are different. Thus a decision must be taken for choosing the clustering method that produce the best data partition for a given data collection.

The objective of the present work is to perform a comparison study between four clustering methods-Complete linkage, Ward's method, K-means method
