10 C-9

APPROVAL SHEET

TITLE OF THE M.Sc. THESIS

**PETROLOGY AND STRUCTURE OF THE BARRAMIYA
AREA WITH SPECIAL EMPHASIS ON THE GOLD
MINERALIZATION, EASTERN DESERT, EGYPT.**

Name of the Candidate

Amir Mohamed Hassan Said

Submitted to the Faculty of Science
Cairo University

Supervision Committee:

Late Prof. Dr. Maher A. Takla

Geology Department – Faculty of Science – Cairo University

Dr. Shawky M. Sakran

Shawky Sakran

Geology Department – Faculty of Science – Cairo University

Head of Geology Department

Fac. of Sci. – Cairo Univ.

Prof. Dr. Ahmed M. El Kammar

Note

The present thesis is submitted to Faculty of Science, Cairo University in partial fulfillment for the requirements of the degree of Master of Science in Geology.

Beside the research work materialized in this thesis, the candidate attended eleven postgraduate courses for one academic year in the following topics:

1. Ore mineralogy.
2. Ore deposits.
3. Rock-forming minerals.
4. Isotope geology.
5. Geochemistry.
6. Igneous petrology.
7. Metamorphic petrology.
8. Plate tectonics and mineralizations.
9. X-ray diffraction and other techniques.
10. Statistics.
11. German Language.

The candidate successfully passed the final examination in these courses held in October 2001.

Prof. Dr. A. M. El Kammar

Head of Geology Department

Acknowledgement

The author is greatly indebted to the **Geology Department**, Faculty of Science, Cairo University for the provided facilities during the progress of this thesis.

The author is indebted to late Prof. **Maher Azmi Takla** for suggesting the point of research, supervising the work, his continuous encouragement and faithful discussion during the progress of the work covered by the present thesis.

I wish to express my grateful thanks and deepest gratitude to Dr. **Shawky Sakran** for his joint-supervision, field work support, encouragement and great help during the progress of this work.

I am deeply indebted to Prof. **Ahmed El Kammar** for his great help during the work of thesis, without his help this thesis can not be in the present form.

Special thanks to Dr. **Abdel Hamid Wagdi El Manawi** for valuable discussion and reading the thesis. Grateful thanks to Prof. **Abdel Aziz Abdel Kader Hussein** and Mr. **Ayman El Badry Maurice** for their great help in analytical work and to Dr. **Mohamed Abdel Wahed** for providing landsat images.

Grateful thanks to Prof. **Hamed Metwalli**, Prof. **Aleya Hafez**, Prof. **Zenab Abdel Kader**, Prof. **Mortada El Aref**, Prof. **Fawzy Basta** and Prof. **Adel Surour** for their help and encouragement during the progress of the work.

Thanks to all my colleagues and friends for their encouragement and help with special thanks Mr. **Adham Refaai**, Mr. **Yasser Medhat**, Mr. **Tamer Nassar** and Miss. **Maha Mohamed Mahmoud**.

To my mother

ABSTRACT

The present study deals mainly with the petrology and structures of the basement rock units outcropping nearby the Barramiya old gold mine between latitudes $25^{\circ} 02' 36''$ and $25^{\circ} 06' 20''$ N and longitudes $33^{\circ} 44' 30''$ and $33^{\circ} 50' 05''$ E. This thesis aims at studying the genesis of the gold deposit in the Barramiya mine ($25^{\circ} 04' 24''$ N - $33^{\circ} 47' 15''$ E) as well as the role of structures affecting the mine site in the process of mineralization.

Comprehensive field, petrographical and geochemical studies revealed that the study area is generally covered by assorted rock units which mainly include; serpentinites and talc-carbonates including quartz – carbonate dyke-like bodies, metagabbros, metapyroclastics, granodiorites, perthitic leucogranites and dykes. In the mine, quartz – feldspar porphyry dyke-like bodies were also recorded.

Major folding affects most of the basement rock units encountered in the area except granitic intrusions. Five alternating syn- and antiforms were encountered extending for about 5 km. The axial planes of these folds strike $N70^{\circ}E$ and the limbs dip steeply 70° - 80° . They are plunging $>80^{\circ}$ in $N70^{\circ}E$ direction. Major faults can be classified into older ductile and younger brittle faults. The ductile faults are mainly represented by the major thrust faults that are related to early stages of subduction and collision tectonics during the formation of the ancient oceanic crust and volcanic island arcs. Major brittle faults in the study area are mainly represented by inferred NNE left-lateral strike-slip faults recorded in the mine site. Major ductile shear zones of E-W to ENE strike occur in the central part of the study area. They reactivate older thrust faults by convergent right lateral movement (transpression) as indicated from the shear sense indicators which comprises S-C fabric, sheath folding, sigmoidal tension veins filled by quartz, asymmetry of boudinaged quartz veins and anastomosing shear planes. These transpressional ductile shear zones were formed during the later stages of collision. The study area is mainly cut by numerous types of dykes; the most important types are the quartz – carbonate dykes and the quartz – feldspar dyke-like bodies. Quartz – carbonate dykes have a general major E-W trend with various length and thickness, mainly associated with serpentinites. Quartz – feldspar porphyry dyke-like bodies, recorded only in the mine site, occur in four main trends E-W to ENE, NE, WNW and NW. The dykes of the first three trends are thinner than that of the fourth trend. The E-W to ENE trending dykes are affected by strong shearing whereas the NW trending dykes are affected by extension fracturing and still show most of their primary textures. The rock units of the study area have undergone a polyphase deformation history. Each single deformational event is defined by a group of structures showing the same strain axis, the same bulk kinematics and the same igneous and/or metamorphic event (s). Three successive deformations called D1, D2 and D3 have been recognized. The P-T conditions of each deformational event were concerned.

The country rocks of the Barramiya old gold deposit are mainly graphite-bearing sheared serpentinites and sheared actinolite-graphite-serpentine rocks as well as quartz carbonate dyke-like bodies, all are injected by quartz – feldspar porphyry dyke-like bodies and quartz veins of different degrees of shearing and deformation. Numerous gold-bearing quartz veins are found cutting across the sheared serpentinites. These veins have different scales (From microscopic to 1m in width), trends (E-W, ENE-WSW, NE-SW, WNW-ESE and NW-SE directions), colors (black, gray and milky) and degree of deformation which are reflected on the color of the vein;

the darker the color of the vein, the higher the degree of deformation. The distribution of gold in both the country rocks and veins was concerned. The genesis of the gold mineralization in the Barramiya mine was discussed and it was thought that the source rock for the gold mineralization is apparently the gold and sulphide rich serpentinites that occur in the mine site and that gold was mainly introduced into the gold-bearing quartz – carbonates and quartz veins found in the mine site in three successive stages. The first stage is mainly during serpentinization process (ocean floor setting), where gold may be introduced in the contemporaneously developed quartz – carbonate dykes via silica liberated in the serpentinization process and CO_2 in the sea water. The second stage is mainly occurred in the earlier phase of the prolonged transpressional event (D2 deformation). The third stage is the most important stage and of the most effective contribution in the mineralization process in the Barramiya old gold mine where it also derives some gold from the above mentioned stages. This stage is mainly related to the intrusion of syn-collisional granitic pluton which is intruded during the prolonged transpressional event (D2 deformation) but mainly after the second stage discussed above. This granitic pluton does not exposed in the mine site, but the presence of the quartz – feldspar porphyry dyke-like bodies (off-shoots) indicates the presence and the shallowness of such pluton.

Contents

Chapter One: Introduction	1
1.1. Location	1
1.2. Aim and scope of study	3
1.3. Methodology	4
1.4. Analytical methods	5
1.5. Previous work	6
Chapter Two: Geological set up	14
2.1. Regional geological framework	14
2.2. Geologic setting of the study area	21
2.2.1. Ophiolites	24
2.2.1.1. Serpentinites and talc-carbonate rocks	24
2.2.1.2. Quartz – carbonate dykes	29
2.2.1.3. Ophiolitic metagabbros	31
2.2.2. Island arc metapyroclastics	35
2.2.3. Intrusive rocks	37
Chapter Three: Structural set up	42
3.1. Regional structures	42
3.2. Major structures	44
3.2.1. Major folds	44
3.2.2. Major faults	50
3.2.3. Dykes	53
3.3. Geometry and Kinematics of deformation	57
3.3.1. Inherited structures	57
3.3.2. D1 deformation and kinematics	59
3.3.3. D2 deformation and kinematics	61
3.3.4. D3 deformation and kinematics	67

Chapter Four: Petrology and geochemistry	70
4.1. Ophiolites	71
4.1.1. Petrography	71
4.1.1.1. Serpentinites and talc-carbonates including quartz – carbonate rocks	71
A- Massive serpentinites	71
B- Sheared serpentinites	76
C- Talc-carbonate rocks	81
D- Quartz – carbonate rocks	83
4.1.1.2. Ophiolitic metagabbros	86
4.1.2. Geochemistry	91
4.1.2.1. Serpentinites and quartz – carbonate rocks	91
4.1.2.2. Ophiolitic metagabbros	97
4.2. Island arc metapyroclastics	100
4.2.1. Petrography	100
4.2.2. Geochemistry	106
4.3. Intrusive rocks	106
4.3.1. Petrography	106
4.3.1.1. Hornblende – biotite granodiorites	106
4.3.1.2. Quartz – feldspar porphyry dyke-like bodies and their sheared varieties	109
4.3.1.3. Perthitic leucogranites	113
4.3.2. Geochemistry of granitic rocks	115
4.3.3. Dykes	118
4.3.3.1. Petrography	118
a- Microgranitic dykes	118
b- Trachyte dykes	121
Chapter Five: Gold mineralization	124
5.1. Introduction	124
5.2. Archaic and recent workings in the mine site	126
5.3. Field relations and observations of the mine site	130

5.4. Petrography and opaque mineralogy of the veins	135
5.5. Geochemistry of the veins	140
5.6. Distribution of gold in country rocks and veins	143
5.7. Discussion on the genesis of gold mineralization	145
5.7.1. Genesis of gold mineralization in Egypt	145
5.7.2. Genesis of gold mineralization in the Barramiya old gold mine	146

Chapter Six: Summary and conclusions	150
