Title of Thesis:

Analytical approach for the assessment of optimum performance propane pre-cooling cycle with aerial cooling in LNG plants .

Key Words:

Aerial cooler, PPMRC, Optimum performance, Aerial mass flow rate, Surrounding ambient aerial temperature.

Summary:

An analytical approach is developed to check the aerial flow rate required for aerial cooler used in a propane pre-cooling mixed refrigerant components cycle operating in a Liquefied natural gas (LNG) plant located at Damietta, Egypt. The presented analytical approach takes into concern the changes in both the ambient air inlet temperature and the aerial mass flow rate. Based on an economic objective function, namely the annual total cost of the aerial cooler, the optimum operating conditions and hence the best performance of the propane pre-cooling mixed refrigerant cycle with aerial cooling was determined for various ambient aerial surrounding temperatures. Two algorithms are presented which can be used effectively with good engineering accuracy to control the process fluid (propane) outlet temperature in the propane precooling cycle through regulation of the air flow rate. The ambient air inlet temperature is modeled analytically by simplifying periodic relations. Numerical results are obtained reflecting the performance of the air-cooled heat exchanger which cools both NG (natural gas) and MR (mixed refrigerant) in the selected LNG plant. The obtained results revealed that the periodic hourly variations of the ambient air inlet temperature in the summertime have a much impact on the required air flow rate, while its influence becomes relatively less pronounced in winter

Acknowledgment

First and foremost, I thank Allah, the most gracious, the ever merciful for helping me finish this work.

I would like to express my full thanks and appreciation to Prof. Dr. Mohammed Fahmy Mostafa for his support, continuous encouragement, useful suggestions and active help during this work.

Nobody has been more important to me in the pursuit of this project than the members of my family. I would like to thank my parents, my brothers and my sisters, whose love and guidance are with me in whatever I pursue. They are the ultimate role models. Most importantly, I wish to thank my I am grateful to all of those with whom I have had the pleasure to work during this. Each of the members of my Dissertation Committee has provided me with extensive personal and professional guidance and taught me a great deal about both scientific research and life in general.

Abstract

An analytical approach is developed for evaluating the hourly performance of an aerial cooling heat exchanger during winter and summer times, as it's in operation into propane pre-cooling mixed refrigerant cycle (PPMRC) at Liquefied natural gas (LNG) plant located at Damietta, Egypt. This analytical approach is taking into consideration the effect of varying two main important variables, the ambient air input temperature (t_{in}) and the aerial mass flow rate (W_{air}) on the design and rating of the aerial cooled heat exchanger .

First, the studying is carried out for searching the effect of varying the aerial mass flow rate (W_{air}) at a constant ambient inlet temperature on several operating parameters such as : the overall heat transfer coefficient (U_{ox}) , the weighted corrected mean temperature difference ($CMTD_{weighted}$), the total extended surface area (A_x), and the layout configuration of the aerial heat exchanger from face area , tube bundle width , and length are included .

Secondly, the effect of varying aerial mass flow rate at a constant temperature on the total power required and the total energy consumed by all of the fans is investigated. The objective of this complex calculations is estimating the total annual cost curve, a curve which is based on an economic function. The annual total cost of an aerial cooler is the summation of operational and fixed cost which annually charged. A list of basic thermodynamics and heat transfer equations are to be demonstrated.

Thirdly, the optimum conditions of an aerial cooler in operation are investigated, as the optimal design conditions are the conditions which the best performance, better operability, the efficient and eventually cost-effective operation of the aerial cooler. The optimum conditions are estimated for different surrounding air input temperature.

Finally, the hourly impact of varied surrounding air temperature on the operation aerial mass flow rate of an aerial cooler is also investigated. As the hourly variations of air temperature during winter and summertime is being represented by simple periodic relations.

An interrelation between the mass flow rate of air (W_{air}) and the ambient temperature (t_{in}) is providing a way for adjustment of process fluid exit temperature. Also, it's a control method for the required amount of aerial mass flow that is displaced and the moved through daily operation and further the seasonally operation. The controlling system is either to be manually via operated louvers or pneumatically through activated automatic variable pitch fan or Variable frequency fan drive (VFD).

Numerical results are obtained showing the performance of the aerial cooling heat exchanger operated in propane pre-cooling which cools both NG (natural gas) and MR (Mixed refrigerant) streams in the LNG plant located at Damietta, Egypt. The input air temperature variation in the summertime has a considerable effect on the required air mass flow rate (W_{air}), while its influence becomes relatively less pronounced in winter. Two algorithms describing the analytical approach derived are presented.
