**Approval:** 29 / 08 / 2018

### ABSTRACT

Potted experiment was conducted on transplants of five olive cultivars "Picual, Hamed, Arbequina, Kalamata and Toffahi" besides four F1 hybrids "H61, H138, H107 and H69" to investigate the impact of salinity (6000 & 9000 ppm and SAR-12) and possibility of alleviating salts hazard through application of some recovering substances (magnetite, potassium silicate and kitasol). Results showed that, survival (%) and vegetative growth parameters (stem length & diameter, laterals & leaves numbers/ plant, leaf area, assimilation area/ plant and fresh & dry weight) were significantly varied depending on the studied salinity level, whereas; all parameters were significantly decreased as salt concentration increased. The physiological parameters revealed two conflicting trends, whereas osmotic potential was increased by salinity, but the reverse was found with transpiration rate. The chemical composition (leaf chlorophyll A & B, carotenoids, Cl, Na, K, Ca, N, P, total soluble sugars and proline) contents, showed two opposite trends i.e., (Cl, Na, Ca, total soluble sugars and proline) increased by salinity, while, the reverse was detected with (chlorophyll A & B, carotenoids, K, N and P). Meanwhile, hybrid 61 behaved as the highest salt tolerant genotype as compared with its relatively salt tolerant parents (Picual & Hamed cvs.), while; hybrid 69 recorded the lowest ones in both seasons. However, such salinity disorders were relatively allayed by any recovering treatments, whereas magnetite were the most effective followed by K-silicate while kitasol had the least effect. In addition, leaf blade thickness upper and lower epidermis and spongy tissues of the olive transplant clearly increased in plants received the high saline water (9000 ppm) compare to the control transplants irrigated with tap water. The highest increase due to saline treatment was recorded for H61 and the least for H69 compared to their maternal parents Hamed and Toffahi. Meanwhile, thickness of palisade tissue, midrib, xylem, phloem and fibers thickness clearly reduce as salinity treatment. However, the salt tolerant of olive genotypes under investigation could be identified by cultivar-specific ISSR markers. Some ISSR markers may be linked to salt tolerance. The TE primer revealed polymorphism in relation to the salt tolerance of the highest salt tolerant genotype (61 hybrid).

**Keywords:** Olive, genotypes, salt stress, magnetite, K-silicate, kitasol, anatomy, ISSR-PCR, salt tolerance.

## **DEDICATION**

*I dedicate this work to my husband for all the support he lovely offered during my post-graduate studies.*

## **ACKNOWLEDGMENT**

*I would like to express my sincerest thanks and gratitude to. **Dr. Mohamed Ahmed Fayek**, Professor of Pomology, Faculty of Agriculture, Cairo University, for his supervision scientific guidance, providing facilities during this investigation, valuable advice, kind encouragement, constructive criticism and expert guidance. I am also indebted to **Dr. Tarek Abd El-Aleem Fayed** Professor of Pomology, Faculty of Agriculture, Cairo University, for his supervision and follow up of the study. Sincere thanks are also due to **Dr. Emtithal Hassan El-Sayed** Head Research of Olive and Semi Arid Fruits, Horticultural Research Institute, ARC, Giza, for her kind help, continuous encouragement and supervision during the preparation of this work.*

*Grateful appreciation is also extended to all staff members of the Olive and Semi Arid Zone Fruits Department, HRI, ARC for the general assistance.*

*Special deep appreciation is given to my husband, my parents, my brother and my sister for their support me.*
