

The Role of Pre-B-cell Colony-Enhancing Factor in Egyptian Children with Hemophagocytic Lymphohistiocytosis

Thesis

*Submitted for the Partial Fulfillment of
Master Degree in **Pediatrics***

Presented by

Reda Mostafa Mohamed

M.B.B.Ch. Ain Shams University 2008

Under Supervision of

Prof. Wafaa Ezzat Ibrahim

Professor of Pediatrics

Faculty of Medicine – Ain Shams University

Ass. Prof. Fatma Soliman Elsayed Ebeid

Assistant Professor of Pediatrics

Faculty of Medicine – Ain Shams University

Dr. Enas Mohamed Hamed Salama

Lecturer of Pediatrics

Faculty of Medicine – Ain Shams University

Faculty of Medicine

Ain Shams University

2018

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

﴿وَعَلَّمَكَ مَا لَمْ تَكُنْ تَعْلَمُ وَكَانَ

فَضْلُ اللَّهِ عَلَيْكَ عَظِيمًا﴾

صدق الله العظيم
سورة النساء آية (١١٣)

Acknowledgment

*First and foremost, I feel always indebted to **ALLAH**,
the Most Kind and Most Merciful.*

*I'd like to express my respectful thanks and profound gratitude to
Prof. Dr. Wafaa Ezzat Ibrahim, Professor of Pediatrics Faculty of
Medicine – Ain Shams University for her keen guidance, kind supervision,
valuable advice and continuous encouragement, which made possible the
completion of this work.*

*I am also delighted to express my deepest gratitude and thanks to
Dr. Fatma Soliman Elsayed Ebeid, Assistant Professor of Pediatrics
Faculty of Medicine – Ain Shams University, for her kind care, continuous
supervision, valuable instructions, constant help and great assistance
throughout this work.*

*I am deeply thankful to **Dr. Enas Mohamed Hamed
Salama**, Lecturer of Pediatrics Faculty of Medicine – Ain Shams
University for her great help.*

*Last but not least my sincere thanks and appreciation to all
patients participated in this study from Paediatric Oncology Unit,
Children Hospital, Ain shams University.*

Reda Mostafa Mohamed

Abstract

Background: Hemophagocytic lymphohistiocytosis (HLH) is a clinical syndrome caused by a highly active but ineffective immune response, including impaired or absent function of natural killer cells and cytotoxic T cells, and the release of pro-inflammatory cytokines. Pre-B-cell colony-enhancing factor (PBEF) is an inflammatory cytokine involved in several inflammatory diseases and it has been identified to react with several cytokines involved in HLH.

Objective: we aimed to evaluate the role of PBEF as a diagnostic and prognostic marker in patients with HLH.

Subjects and Methods: The study was conducted at the pediatric hematology oncology unit, Ain Shams University. Fifteen patients were recruited and underwent through clinical assessment lying concentration on disease manifestation, classification, treatment and prognosis. Plasma concentration of PBEF was determined using an enzyme-linked immunosorbent assay.

Results: PBEF level was measured in the patients group, it was highly significantly increase for patients group than control group. Four patients were classified as primary HLH, seven patients were classified as secondary HLH and four patients had unknown classification due to waiting for genotyping. Seven patients of the study group were died and eight patients still alive. PBEF level showed a significant positive correlation with serum ferritin and triglycerides level and negative correlation with fibrinogen level.

Conclusion: An elevated PBEF level was observed in pediatric HLH, indicating that it may be involved in its inflammatory process. PBEF was correlated with the widely available biochemical markers for diagnosis of HLH.

Keywords: Childhood, Cytokine, Hemophagocytic lymphohistiocytosis, Pre-B-cell colony-enhancing factor.

INTRODUCTION

Hemophagocytic lymphohistiocytosis (HLH) is a clinical syndrome caused by a highly active but ineffective immune response, including impaired or absent function of natural killer cells and cytotoxic T cells, and the release of pro-inflammatory cytokines (*Freeman and Ramanan, 2011*).

Patients with HLH present with a wide spectrum of clinical manifestations and their conditions may rapidly deteriorate, resulting in considerable morbidity and mortality. The primary form, familial HLH, typically seen during infancy and early childhood, is inherited as a recessive trait (*Henter et al., 2007*). Adult-onset HLH is often secondary to an underlying disease, such as infection, malignancy, or autoimmune disease (*Janka, 2007*).

Treatment of patients with HLH aimed to suppress the severe hyperinflammation, and to kill pathogen-infected antigen presenting cells to remove the stimulus for the ongoing, but ineffective activation of cytotoxic cells, it should be emphasized that it is usually not sufficient to treat an identified organism to control hyperinflammation with the possible exception of leishmania-induced HLH, which in most patients can be treated successfully with liposomal amphotericin only. In genetic cases the ultimate aim is stem cell transplantation to exchange the defective immune system by normally functioning cells. Treatment should be guided primarily by the

severity of signs and symptoms, but also known familiarity of the disease, age of the patient and underlying conditions have to be considered (*Janka and Schneider, 2004*).

Initial therapy in patients with hemophagocytic lymphohistiocytosis (HLH) consists of etoposide and dexamethasone for 8 weeks in varying doses. In the HLH-2004 protocol, cyclosporine is added in the beginning. Intrathecal methotrexate is used only with persistently abnormal CSF or progressive neurologic symptoms. Resolved nonfamilial hemophagocytic lymphohistiocytosis does not require continuation of the therapy regimen unless disease reactivation occurs after completion of the initial therapy or unless patients are undergoing bone marrow transplantation (BMT). For the remaining children with persistent nonfamilial disease or familial disease, continuation therapy with etoposide IV infusions, dexamethasone pulses, and cyclosporine PO is instituted at week 9 from the start of initial treatment (*Henter et al., 2002*).

Pre-B-cell colony-enhancing factor (PBEF) is an inflammatory cytokine involved in several inflammatory diseases (*Gao et al., 2015*). It was first identified as a cytokine that acted synergistically with interleukin (IL)-7 and stem cell factor to stimulate early stage B cell formation (*Samal et al., 1994*). PBEF has been identified to react with several cytokines involved in HLH (*Osugi et al., 1997*).

AIM OF THE WORK

Evaluation of the role of pre-B-cell colony- enhancing factor (PBEF) as a diagnostic and prognostic marker in children with hemophagocytic lymphohistiocytosis.

The study also aimed to study the clinical epidemiological characteristics of hemophagocytic lymphohistiocytosis.

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH)

Hemophagocytic lymphohistiocytosis (HLH) is a severe inflammatory disorder characterized by a significant accumulation of activated CD8⁺ T lymphocytes and histiocytes in the bone marrow (BM) and lymphoid tissues. The cytokine storm resulting from the accumulation of activated immune cells leads to fever, hepatosplenomegaly, impaired liver function and other clinical and laboratory manifestations of HLH (*Filipovich, 2009*). Classically, HLH is divided into primary or familial HLH (FHL) and secondary HLH (sHLH). FHL, which is an autosomal recessive disease, is caused by mutations in the genes encoding the molecules involved in the granule exocytosis machinery of cytotoxic T lymphocytes and natural killer (NK) cells. Although the pathogenesis of sHLH is largely unknown, the two forms of HLH, or sHLH and FHL, have similar clinical characteristics (*Janka, 2007*).

Epidemiology:

Defining the true incidence is an impossible task as HLH is a condition that some consider a faith-based diagnosis, making the phenotype of the provider as important as the patient to identify and report “HLH” versus other conditions characterized by inflammation (*Castillo and Carcillo, 2009*). The Swedish national registry provides the a rigorous estimate

the incidence of primary HLH with 1.5 cases/million live births in Sweden 2007-2011, up slightly from 1.2 cases/million in previous studies (1987-1996, 1997-2006) (*Meeths et al., 2014*).

In North America, frequency of specific gene defects varies significantly with ethnicity/race (*Jordan et al., 2011*).

The disease is seen in all ages and has no predilection for race or sex (*Janka, 2012*).

Pathophysiology:

In the normal physiological context, granule-mediated cytotoxic function of natural killer (NK) cells and cytotoxic T lymphocytes (CTLs) is required for clearance of viral infection as well as regulation and termination of the inflammatory response (*Lykens et al., 2011*).

Thus, defects in NK cell and CTL granule-mediated cytotoxicity result in ineffective clearance of infection and defective suppression of antigen presentation, leading to persistent antigen exposure and prolonged cytotoxic T-cell activation (*Lykens et al., 2011*). Until recently, the pathophysiology of secondary HLH was not well understood. However, the finding of an HLH/MAS like condition from repeated Toll-like receptor 9 stimulation in a murine model could explain the potential mechanism of HLH in inflammatory conditions with normal T-cell cytotoxicity (*Behrens et al., 2011*). IFN- γ has been shown to play a critical role in macrophage activation and hemophagocytosis (*Zoller et al., 2011*).
