Acknowledgments

I gratefully acknowledge the "Institut Français d'Egypte" for the funding sources that made my Ph.D. work possible. I would like greet the French Institute of Egypt which, by supporting Egyptian researchers to come to France, gives them the opportunity to deepen the relations between the two peoples, thus allowing a better understanding between our civilizations

I would like to express my sincere gratitude to my advisor Dr. Didier Desmaële for the continuous support of my Ph.D study and related research, for his patience, motivation, and immense knowledge. His guidance helped me in all the time of research and writing of that thesis. I could not have imagined having a better advisor and mentor for my Ph.D study.

Also, I am also grateful to Dr. Phillipe Collery and his organization (Société de Coordination de Recherche Thérapeutique, Bastia, France) for his endless enthusiasm for metallodrugs and his material and psychological support during my Ph.D stays in France.

I'd like to thank Professor/ Gilane Mohamed Sabry, Professor/ Abd Elfattah Badawi and Dr. Rasha Elshrif for their co-supervision and their support into Faculty of Science, Ain Shams University and Egyptian Petrloleum Research Institute.

My sincere thanks also go to Professor/ Hamid Morjani, who helped me during my stay in Reims University. I would like to show him and his family my respect and appreciation and thank him for his kind hospitality. I would like to thank him for providing the opportunity to join his team as trainee, with full access to the laboratory and research facilities. Without his precious support it would not be possible to conduct this research.

Also, I am sending all my grateful to Dr. Pierre Jeannesson, Dr. Roselyne Garnotel, Dr. Bertrand Brassart and Dr. Nicolas Etique for their help and support during fulfillment of the biological experiments.

Finally, I would also like to acknowledge Professor/ Elias Fattal and Professor Patrick Couvreur for allowing me to join the Institut Galien

Aim of the work

Aim of the work

It was shown in the 1980s that gallium (III) ions may have anti-tumor activity in animals. Unfortunately, clinical trials with simple gallium salts failed because of the low bioavailability of oral gallium salts, renal toxicity and the rapid onset of gallium resistance. Furthermore, gallium salts hydrolyse rapidly to insoluble gallium hydroxide. A solution to these problems consists in the complexation of the metal by a ligand. A number of effective ligands have been proposed, demonstrated promising results in preclinical studies and have entered clinical trials but with limited water solubility. In this context there is a need to identify a gallium ligand able to preserve the gallium from the hydrolysis while maintaining water solubility.

To address this issue, the present study was designed to prepare, synthesize and characterize the chemical structure of water soluble bioavailable gallium complex(es) by using different chemical analyses methods. This work was also pre-designed to evaluate the anti-invasion capabilities of the novel synthesized gallium complex(es) through inspecting their inhibitory effect over some collagenase enzymes such as (MMP-2 and MMP-9 and MMP-14) as a possible promising mechanism to control the invasion of some metastatic tumors where, studies that touched that goal were scarce. Moreover, an intensive biological study was performed to evaluate the antitumor activity, possible mode of action including reactive oxygen species activity, early and late stage apoptotic, Phosphoinositide-3 kinase/Protein kinase B pathways and collagenases inhibitory action of the tested gallium complex(es).

Abstract

Abstract

It was shown in the 1980s that gallium salts may have anti-tumor activity in animals. Unfortunately, clinical trials with either nitrate or gallium chloride have failed for a variety of reasons including low bioavailability, renal toxicity, and rapid onset of gallium resistance. So, the main task of our work was to prepare and characterize the chemical structure of some new water-soluble bioavailable gallium complexes derived from aspartic acid and to study their possible biochemical effects on the activity of metalloproteinases (collagenases) as a possible promising mechanism to control the invasion of some metastatic tumors.

In the present study, two water soluble gallium complexes with formula $[\text{Ga(III)LCl}]$, where L stands for the deprotonated form of N-2-hydroxybenzyl aspartic acid derivatives that were synthesized and characterized by ^1H NMR, ^{13}C NMR, FT-IR, mass spectrometry and elemental analysis. The analytical data are consistent with a mononuclear structure in which the gallium (III) cation is liganded by one of the two carboxylic acid groups, the phenol oxygen and the nitrogen atom of the 2-hydroxybenzylamino group. In such a structure, the tridentate ligand secures the binding of the metal ion whereas the carboxylic appendage provides the water solubility. The cytotoxicity of the gallium complex of (R)-2-(5-chloro-2-hydroxybenzylamino) succinic acid (GS2) was evaluated against human breast carcinoma MDA-MB231 and fibrosarcoma HT-1080 cell lines. The 5-chloro derivative GS2 was found to be more cytotoxic than the unsubstituted derivative and GaCl_3 . GS2 induces apoptosis through down-regulation of AKT phosphorylation, G2M arrest in cell cycle *via* activation of the caspase3/7 pathway. Although, many molecular and cell effects of Ga

have been described, including proteasome inhibition and osteoclastic activities, GS2 appears as the first gallium compound able to decrease AKT phosphorylation in cancer cells. The activity of GS2 on cell invasion and on the expression and activity of Matrix Metalloproteinases (MMPs) was investigated using modified Boyden chamber coated with type I collagen. The activity of MMPs was analyzed by zymography and enzymatic assay using high affinity fluorogenic substrates. A selective inhibition of MMP-14 has been reported to block tumor cell migration and invasion. The expression of MMPs mRNA was analyzed by qRT-PCR. GS2 induces a decrease in cell invasion. A dose dependent inhibition effect was observed on MMP-2, MMP-9 and MMP-14 activities. A decrease in MMP-14 mRNA expression was observed in both cell lines, whereas MMP-2 and MMP-9 mRNA expression was decreased only in MDA-MB231 cells. Thus, the present study proposes that GS2 compound may be a potential candidate to decrease the MMP-14 activity in cancer metastatic diseases presenting high level of MMP-14 expression and activity. Taken together, these data show that the possible future combination of GS2 with cytotoxic chemotherapy may be considered one of the promising treatment modes for anti-invasive and anticancer therapy.
