Acknowledgement

First and foremost I am grateful to **ALLAH** for giving me the opportunity to complete this study, and give Him thanks and praise. My special thanks and gratitude to **Dr. Manal Salah Hassan** Professor of Medical Surgical Nursing, Faculty of Nursing, Ain Shams University I am deeply grateful to her guidance, constructive criticism, keen supervision, encouragement and continuous support. I would like to address my great appreciation and thanks to **Dr. Zeinab Hussien Bakr** Lecturer of Medical Surgical Nursing, Faculty of Nursing, Ain Sham University and **Dr. Eman Fathy Amr** Lecturer of Medical Surgical Nursing, Faculty of Nursing, Beni-Suef University for all their support, guidance, their close supervision, critical comments and careful revision of the work helped much in its achievement. Finally, I would like to thank all members of my family and unknown soliders for continuous support and assistance in every step in the journey of my life.

Candidate

Abstract

Intensive Care Unit Acquired Muscle Weakness (ICU-AW) is one of the most important complications occurs in the ICU. It is a multifactorial syndrome characterized by generalized muscle weakness. Critical Care Nurses (CCNs) have an important role in the prevention of ICU-AW through increase mobility and applying of range of motion (ROM) exercise. **Aim:** This study aimed to assess factors contributing to acquired muscle weakness among critical ill patients. **Design:** A descriptive explorative design was utilized for the conduction of this study. **Setting:** the study was carried out in intensive care units (ICUs) of Beni-Suef University Hospital (general, chest and internal medicine ICU). **Study subject:** A Purposive sample of seventy five patients admitted to the previous mentioned setting. **Tools of data collection were consisted of** patient assessment tool, muscle strength scale /medical research council (MRC) and indicators to incidence of ICU-AW, and factors contributing to ICU-AW assessment tool. **Results:** revealed that, more than half of studied patients had ICU-AW, the majority of studied patients who had muscle weakness were older than the Non ICU-AW patients. Application of positioning and range of motion exercises were not done in the ICU-AW patients. Administration of corticosteroid and incidence of malnutrition was higher in the ICU-AW patients than the Non ICU-AW patients. There were no statistically significant relation between incidence of ICU-AW and gender, admission medical diagnosis, administration of parenteral nutrition and application of positioning, and walking exercises. **Conclusion:** More than half of studied patients developed ICU-AW. The contributing factors of ICU-AW are patient age, WBCs level, no applying range of motion and chair sitting exercise to ICU patients, administration of corticosteroid and malnutrition. **Recommendations:** Further research is recommended to study extensively the effect of nutritional status on incidence of ICU-AW. Also, examine the incidence of ICU-AW in sedated and unconscious patients.

Introduction

Intensive Care Unit Acquired Muscle Weakness (ICU-AW) is one detrimental effect of critical illness on physical function. This term refers to a wide variety of disorders characterized by acute onset of neuromuscular impairment for which there is no other plausible cause than the critical illness. It is characterized by bilateral symmetrical flaccid weakness of the limbs, facial and ocular muscles are often spared, and deep tendon reflexes are usually reduced (*Castro, Seron, Fan, Gaete & Mickan, 2015*).

Intensive care unit (ICU) patients has identified with generalized muscle weakness and represent about 70 -80 % of admitted patients. There are different terminology used to define this generalized weakness, a critical illness associated polyneuropathy, myopathy and neuromyopathy have broadly been identified. These syndromes are now all included under the clinical diagnostic label of ICU-AW (*Appleton, Kinsella & Quasim, 2015*).

The reported incidence of ICU-AW varies depending on the patient, timing of assessment and diagnostic methods used. ICU-AW is common and range from 26 - 65% for patients intubated for a duration of 5-7 days, and

up to 67% of patients with prolonged periods of intubation (>10 days) (*Wieske et al., 2015*).

Intensive Care Unit Acquired Muscle Weakness (ICU-AW) persisted for at least another 7 days following extubation in an estimated 25% of those ICU patients. In patients with acute respiratory distress syndrome (ARDS), an estimated 60% of them develop ICU-AW. The incidence of ICU-AW is significantly higher in individuals with sepsis and has been reported to be as high as 50 –100 % (*Nakamura & Yonclas, 2017*).

Intensive Care Unit Acquired Muscle Weakness (ICU-AW) is classified to critical illness polyneuropathy (CIP), critical illness myopathy (CIM), or both. CIP refers to diffuse and symmetric sensorimotor axonal neuropathy and observe a distal loss of sensitivity to pain, vibration, and temperature, and often the patients have difficult to breathe spontaneously or to be weaned from mechanical ventilation due to phrenic nerve and diaphragm involvement (*McWilliams, Weblin & Atikns, 2015*).

Critical illness myopathy (CIM) occurs more frequently than CIP and patients characteristics include early loss of muscle tissue, but with conservation or slightly reduced deep tendon reflexes. In critical illness
