# *Acknowledgment*

First and foremost, I thank **ALLAH** who gave me the strength to accomplish this work

Special thanks to ***Prof. Dr. Fatma Salah Eldein*** , Professor of Radiology, Ain Shams, for giving me the honor to work under her supervision, valuable advices, continuous encouragement and kind support at this study.

Words can never express my feelings, respect and gratitude to ***Dr. Nivine Abd Elmonem Chalabi*** Assistant Professor of Radiology, Faculty of Medicine, Ain Shams University for her continues care, support and for her invaluable guidance, constructive criticism in supervising this work.

My deep appreciation to ***Dr. Nermeen Nasry***, Lecturer of Radiology, Ain Shams University, for her great assistance and precious advice. Your moral support, words of encouragement and faith in all your candidates is inspiring to all of us.

I am also very grateful to ***Dr. Zenab Mostafa***, Fellow of Radiology National Hepatology & Tropical Medicine Research Institute for her kind guidance throughout the whole work.

Special Thanks to my friends & fellow colleagues in the Radiology Department, National Hepatology & Tropical Medicine Research Institute.

I would like to express my eternal appreciation towards my family and my dearest husband who have always been there for me wherever I am, for their unconditional support and patience.

# Abstract

Recent developments in diagnostic imaging techniques have magnified the role and potential of MRI in female pelvic imaging. Functional imaging by means of dynamic multiphase contrast-enhanced magnetic resonance imaging (DCE-MRI) and diffusion weighted magnetic resonance imaging (DW-MRI) is now part of the standard imaging protocols for evaluation of the female pelvis.

In this review, we give an overview of both DCE-MRI and DW-MRI techniques, concentrating on their main clinical application in preoperative staging and their role in tail or in treatment options and therapy in patients with uterine malignancies. We were aiming to compare DW-MRI with DCE-MRI in a way to highlight the most cost effective method in management of patients with uterine malignancy.

DCE-MRI improves the accuracy of T2WI in staging of endometrial cancer. It also increases reader's confidence in assessment of parametrial infiltration and adjacent organ invasion in cancer cervix. DW-MRI is valuable in preoperative staging of patients with endometrial and cervical cancer, specially in detection of extra-uterine disease. It increases the confidence for detection of recurrent disease in uterine malignancies and improves detection of small peritoneal implants.

**Key words:** endometrial carcinoma, cervical carcinoma, dynamic contrast enhanced MRI, Diffusion weighted MRI, functional imaging.

# Introduction

Endometrial carcinoma is the most common gynecological malignancy and the sixth most common neoplasm worldwide. It typically presents with abnormal uterine bleeding in 75% to 90% of patients. (*Jemal et al, 2011*)

Uterine cervical cancer is the fourth most common female malignancy and has a high mortality rate. Most women with cervical cancer are diagnosed before the age of 50. However; older women remain at risk. More than 20% of new cases are diagnosed in women over 65. Cervical cancer in women younger than age 20 is rare. (*Ferlay et al, 2015*)

The treatment planning depends on staging of the tumor; therefore pre-operative assessment is closely related to patient survival and prognosis. (*Zheng et al, 2015*)

The traditional and reliable staging of endometrial carcinoma relies on the surgical staging system, which was revised in 2009 by the International Federation of Gynecology and Obstetrics (FIGO). Therefore, there is a clinical need for noninvasive imaging modalities that can provide accurate preoperative staging information for endometrial carcinoma. (*Zheng et al, 2015*)

Magnetic resonance imaging (MRI) is considered a noninvasive method giving excellent soft tissue contrast resolution with multiplanar capabilities when evaluating the female pelvis. (*Zheng et al, 2015*); It depicts the key prognostic factors such as depth of myometrial invasion, cervical stromal & pelvic lymph nodes involvement preoperatively, thus it plays an increasing role in clinical decisions regarding endometrial carcinoma. (*Rauch et al, 2014*)

Cervical cancer is the only gynecologic malignancy that is still clinically staged according to the revised 2009 FIGO classification system. However, the committee encourages the use of imaging as clinical staging is inaccurate in 22%–75% of

patients. The use of MRI can detect the tumor extension into the lower part of the uterus, para-metrium, and para-cervical fat thus enables patients to be more appropriately triaged for hysterectomy or chemoradiation therapy. *(Rauch et al, 2014)*

Thus MRI now has an established role in staging, management & follow up of the tumor. Both clinicians and radiologists currently agree that MRI is superior to transvaginal sonography and CT. *(Zheng et al, 2015)*

DCE-MRI improves the accuracy of T2WI in staging of uterine cancer and is highly accurate in evaluating the depth of myometrial invasion as the majority of tumors are hypovascular compared to the adjacent enhancing myometrium. *(Sala et al, 2010)*

In spite of being the standard modality for evaluating gynecological malignancies but MRI has several limitations. Consequently, there has been a growing interest in functional imaging modalities. Diffusion-weighted imaging (DWI) with the aid of quantitative apparent diffusion coefficient (ADC) measurement is a unique, noninvasive modality that was shown to improve the radiological diagnosis of malignant tumors. *(Levy, et al, 2011)*

Diffusion-weighted magnetic resonance imaging (DW-MRI) is a functional imaging technique whose contrast derives from the random motion of water molecules within tissues, thus no exogenous contrast medium administration is required, so that diffusion-weighted sequences can now be included in routine patient assessment. *(Whittaker et al, 2009)*
