

***Thyroid Imaging, Reporting and Data System  
(TI-RADS) in differentiation between benign  
and malignant thyroid nodules***

A THESIS SUBMITTED FOR PARTIAL FULFILMENT  
OF MASTER DEGREE IN RADIOLOGY

---

**Presented by**

**Mikel Naguib Melad Abdo**

M.B.B.CH. – Ain Shams University

**Supervised by**

**Assistant Prof. Dr. Enas Ahmed Azab**

Assistant Professor of Radiodiagnosis

Faculty of Medicine

Ain Shams University

**Dr. Ahmed Samy Abdelrahman**

Lecturer of Radiodiagnosis

Faculty of Medicine

Ain Shams University

**Faculty of Medicine**

**Ain Shams University**

**2018**

# ACKNOWLEDGEMENT

---

*First, I thank **God** for blessing me more than I deserve and for his uncountable gifts which are exceeding abundantly above all what we ask or think,*

*I would like to express my deepest appreciation and gratitude to **Assistant Prof. Dr. Enas Ahmed Azab** for her sincere encouragement, constant advice and valuable guidance throughout the performance of this work,*

*I owe special thanks, gratitude and appreciation to **Lecturer. Dr. Ahmed Samy Abdelrahman** for his close supervision, continuous advice and support which gave me the best guidance during different stages of this work,*

*Finally, I cannot forget to thank my professors, my family, and my colleagues, for their support and encouragement.*

# INTRODUCTION

---

Thyroid nodules are exceedingly common, with a reported prevalence of up to 68% in adults on high-resolution ultrasound. **(Guth et al., 2009).**

Thyroid nodules have been defined by the American Thyroid Association (ATA) as “discrete lesions within the thyroid gland, radiologically distinct from surrounding thyroid parenchyma”. **(Cooper et al., 2009).**

Thyroid nodules are clinically important for several reasons. They may cause thyroid dysfunction and, rarely, compressive symptoms, but they are primarily important because of the need to exclude thyroid cancer. **(Lin et al., 2005).**

Thyroid ultrasound is an important technique widely used in the detection and evaluation of thyroid nodules. It is a non-invasive and inexpensive procedure that provides information with regard to nodule dimensions, structure and thyroid parenchymal changes. Nowadays, the use of brightness-mode US and high-frequency transducers may detect lesions as small as 2 to 3 mm. **(Geanina and Jacqueline, 2012).**

Several authors have recently described a standardized risk stratification system called the Thyroid Imaging, Reporting and Data System (TI-RADS). **(Grant et al., 2015).**

Much of this shift toward data - driven and linked outcomes based reporting templates comes from the success of the BI-RADS system for standardizing mammography reports. BI-RADS improved interpretation of imaging findings, and management recommendations guidance. Similar templates have been developed for hepatocellular carcinoma, thyroid nodules, and prostate cancer. **(Dodd et al., 2015).**

TI-RADS is a reporting system for thyroid nodules on ultrasound proposed by the American College of Radiology (ACR). The ultrasound features in the ACR TI-RADS are categorized as benign, minimally suspicious, moderately suspicious, or highly suspicious for malignancy. Points are given for all the ultrasound features in a nodule, with more suspicious features being awarded additional points. **(Tessler et al., 2017).**

Scoring is determined from five categories of ultrasound findings (composition, echogenicity, shape, margin and presence of echogenic foci). The higher the cumulative score, the higher the TI-RADS level and likelihood of malignancy. **(Grant et al., 2015).**

The total point determines the nodule's ACR TI-RADS level, which ranges from TR1 (benign) to TR5 (high suspicion of malignancy). **(Park et al., 2016).**

# AIM OF WORK

---

The objective of this study is evaluate the role of Thyroid Imaging, Reporting and Data System (TI-RADS), recently created by the American College of Radiology (ACR) Committee in differentiation between benign and malignant thyroid nodules.

# ANATOMY AND SONOGRAPHIC ANATOMY OF THE THYROID GLAND

## NORMAL THYROID GLAND ANATOMY

The thyroid is a highly vascular, brownish-red gland located anteriorly in the lower neck at the level of the thoracic inlet, extending from the level of the fifth cervical vertebra down to the first thoracic vertebra. **(Dominique, 2017).**

The gland varies from an H to a U shape and is formed by 2 elongated lateral lobes with superior and inferior poles connected by a median isthmus, with an average height of 12-15 mm, overlying the second to fourth tracheal rings. **(Figure 1) (Dominique, 2017).**

Each lobe is approximately 4 cm in length, 2 cm in width, and 2 to 3 cm in thickness. The isthmus measures about 2 cm in width, 2 cm in height, and 2 to 6 mm in thickness. **(Lai et al., 2005).**

Occasionally, the isthmus is absent, and the gland exists as two distinct lobes. **(Dominique, 2017).**

Although thyroid weight varies, it averages 25-30 grams in adults (it is slightly heavier in women). The gland enlarges during menstruation and pregnancy. **(Dominique, 2017).**
