Approval: 10/1/2019

ABSTRACT

Tomato crops (Solanaceae), usually attacked by many insect species, including the tomato leafminer, *Tutaabsoluta* (Meyrick), where its larvae cause damage up to 80-100% by making tunnels in all tomato parts. The physico-chemical properties of 12 commercial insecticides (five EC, four SC, two SG, and one WG) as well as nine naturally formulated compounds (seven EC and two W/O/W) were measured. All the tested formulations passed the tests except Action Phos and Pestbans since they failed in the foam formation test. The efficiency of these formulations was examined against *T. absoluta* under laboratory and field conditions. The laboratory evaluation of the tested commercial insecticides demonstrated that the non-conventional insecticides Emperor and Coragen, achieved the superior efficiency with the least LC₉₀ values of 1.66 and 1.82 ppm, respectively, followed by Proclaim, Radiant, Vapcomic, and Challenger that gave high efficacy with LC₉₀ values of 3.72, 4.84, 8.09, and 164.56 ppm, respectively. Also the naturally formulated compounds were arranged in a descending order according to LC₉₀ values as follows: Thymo "w/o/w" > Corian > Origo > Sagix > Rosa > Nimbecidine > Thymo "EC" > Cura > Menthos > Basi. The most promising commercial insecticides (Emperor, Coragen, Radiant, Vapcomic, and Challenger) as well as six naturally formulated compounds Thymo "w/o/w", Corian, Origo, Sagix, Rosa, and Nimbecidine were applied in the field.

Data showed that, concerning commercial insecticides, generally average reduction of infestation 7 DAT clarified that Emperor insecticide showed the superior reduction in infestation (98.74%) followed by Coragen (95.51%), then Vapcomic, Radiant and Challenger which recorded about 87.75, 88.48 and 84.89%, respectively. Regarding naturally formulated compounds, In general, the mean reduction in infestation during the last three periods (3, 5 and 7 DAT) showed that Nimbecidin, Rosa, Thymo and Origo resulting in a high reduction in infestation with means of (82.70, 79.67, 79.55 and 77.58%, respectively). The influence of insecticides sequence and insect traps application as a strategy for *T. absoluta* management was carried out. Sex pheromone and sticky traps were used for mass trapping this pest; sex pheromone traps were more effective than the sticky one. When the first infestation appeared, the non-conventional insecticides were consecutively sprayed as follows; Radiant, followed by Coragen and then Emperor (during the vegetative stage). After that during the fruiting stage the formulated essential oils Nimbecidine (commercial) and Rosa (Prepared) were respectively sprayed (during the fruiting stage). The general average of reduction in infestation reached 95.81% when non-conventional insecticides were used. Whereas, it reached 92.15% when the formulated essential oils were used.

Key words: insecticides, *Tutaabsoluta*, Emperor, Coragen, formulations, physico-chemical properties.

DEDICATION

I dedicate this work to whom my heartfelt thanks to parents, brothers and sister who have always been a constant source of support and encouragement during the challenges of my whole college life, as well as to my wife and my kids Mahmoud, Mmohamed, Mariam and Malak for all the support they lovely offered, for their patience and help along the period of my post graduation.

ACKNOWLEDGEMENT

Firstly, my obedience and deepest thanks to ALLAH, who has created us and has not, left us without guidance.

Great thanks and gratitude is extended to Dr. Mohamed Abdel-Hady Kandil, Professor of Pesticide, Department of Economic Entomology and Pesticides, Faculty of Agriculture, Cairo University for his supervision, extending his help in many ways throughout these studies.

The author wishes to express his sincere thanks and deep appreciation to Dr. Elham Ahmed Sammour, Researcher Professor of Pesticide, Plant Protection Dept. National Research, Center for supervision, kind guidance, helpfulness, continuous encouragement and invaluable assistance in writing and reviewing the manuscript until this work was completed.

I am grateful to Dr. Essam Abd El Maguied Agamy Professor of Biological control, Department of Economic Entomology and Pesticides, Faculty of Agriculture, Cairo University for his kind help, supervision and encouragement.

*I am also grateful to **Dr. NAHED FAWZY ABDEL-AZIZ** Assistant Researcher Professor of Pesticide, Plant Protection Dept. National Research Center, for supervision, for her kind help and her co-operation in carrying out a part of this work,*

*I am also grateful to **Dr. AHMED MOHAMED EL-BAKRY**, Researcher of Pesticide, Plant Protection Dept. National Research Center, for supervision.*

*I am also grateful to **DR. WAEL AHMAD EZATELABD**, Head of Research - Department of Economic Analysis of Commodities- Agricultural Economics Research Institute - Agricultural Research Center, for helping me in statistical analysis and economic comparative.*

Grateful acknowledgement is expressed to the National Research, Center for all facilities provided for this work,

Finally, I have to deeply thank to my family for their support, patience and encouragement during this research work,

INTRODUCTION

Tomato plant (*Lycopersicon esculentum* L.), which belongs to family Solanaceae, is an important and profitable vegetable crop for fresh market and processing (Abdelrazig *et al.*, 2015; Kushwaha *et al.*, 2018).

In Egypt, tomato crop is the first horticultural crop, where it occupies 440200 feddan which representing 40% of the total cultivated area devoted to vegetable production, yielding 7.73 M tons. (According to the Ministry of Egyptian Agriculture, 2015). Also, FAO classified Egypt during 2017 as the 5th country around the world in tomato production; ~ 6.3% of the tomato production of the world which represent 8.3 M ton (FAOSTAT, 2017).

Tomato crops (Solanaceae), are usually attacked by a great variety of insect pests, including the tomato leafminer, *Tuta absoluta* (Meyrick). It belongs to Lepidoptera: Gelechiidae, and represents the most important pest on tomato and other Solanaceous plants (e.g. eggplant, potato, sweet pepper and tobacco) as well as on some non-cultivated Solanaceae (*Solanum nigrum* L., *S. eleagnifolium* L., *S. bonariense* L., etc.) and other host-plants (e.g. *Datura ferox* L., *D. stramonium* L. and *Nicotiana glauca* Graham). Moreover, other additional plant species have been reported as alternative hosts (e.g. Cape gooseberry (*Physalis peruviana*, *Phaseolus vulgaris*, *Lycium sp.* and *Malva sp.*) (Caponero, 2009; Garzia, 2009). Hence, it is clear that *T. absoluta* can use various plant species as secondary hosts, notably
