

Evaluation of Serum Interleukin 36 in Egyptian Acne Vulgaris Patients versus Controls

Thesis

*Submitted for Fulfillment of Master's Degree
in Dermatology, Venereology & Andrology*

By

Esraa Mahmoud Awaad
M.B.B.CH

Under Supervision of

Dr. Maha Mohamed Adel Shaheen

*Professor of Dermatology, Venereology and Andrology
Faculty of Medicine, Ain Shams University*

Dr. Marwa Yassin Ahmed Soltan

*Lecturer of Dermatology, Venereology and Andrology
Faculty of Medicine, Ain Shams University*

Faculty of Medicine - Ain Shams University

2019

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قالوا

سبحانك لا علم لنا
إلا ما علمتنا إنك أنت
العليم العليم

صدق الله العظيم

سورة البقرة الآية: ٣٢

Acknowledgments

*First and foremost, I feel always indebted to **Allah** the Most Beneficent and Merciful.*

*I wish to express my deepest thanks, and appreciation to **Prof. Dr. Maha Mohamed Adel Shahin**, Professor of Dermatology, Venereology and Andrology, Faculty of Medicine, Ain Shams University, for her kind guidance, valuable instructions and generous help.*

*I wish to extend my gratitude to **Dr. Marwa Yassin Ahmed Soltan**, Lecturer of Dermatology, Venereology and Andrology, Faculty of Medicine, Ain Shams University, for her sincere efforts and meticulous supervision.*

*I am deeply thankful to **Dr. Christine Kamal**, Lecturer of Dermatology, Venereology and Andrology, Faculty of Medicine, Ain Shams University, for choosing the topic and her guidance through the protocol.*

I would like to express my gratitude to all my family for their support till this work was completed.

Esraa Mahmoud Awaad

1. INTRODUCTION

Acne is a multifactorial inflammatory disease affecting the pilosebaceous follicles of the skin. The current understanding of acne pathogenesis is continuously evolving. Key pathogenic factors that play an important role in the development of acne are follicular hyperkeratinization, microbial colonization with *Propionibacterium acnes*, sebum production, and complex inflammatory mechanisms involving both innate and acquired immunity. In addition, studies have suggested that neuroendocrine regulatory mechanisms, diet, and genetic and nongenetic factors all may contribute to the multifactorial process of acne pathogenesis (*Zaenglein et al., 2016*).

Interleukin (IL)-36 sub-family members are new cytokines of IL-1 family that include IL-36 α , IL-36 β , IL-36 γ , and IL-36 receptor antagonist (Ra). IL-36 cytokines are mainly expressed in keratinocytes and monocytes/macrophages and play an important role in the modulation of T helper (Th) 1 and Th17 immune responses. Since IL-36 cytokines are mainly expressed in epithelial cells, particularly in keratinocytes, they have been predominantly studied in skin diseases (*Gresnigt and van de Veerdonk, 2013*).

It has been reported that an imbalance in IL-1 family agonist and antagonist functions could play an important role in cutaneous inflammation and in the phenotype of skin damage;

in particular, genetic deficiency of IL-36Ra may lead to an autoinflammatory condition which primarily manifests as a severe form of pustular psoriasis. Therefore, IL-36 cytokines have been studied in other two important inflammatory skin disorders, such as acne and hidradenitis suppurativa (***Di Caprio et al., 2017***).

2. AIM OF THE WORK

The aim of this study is to compare the level of serum IL36 in acne vulgaris patients versus controls and to find out any possible correlation between its serum level and severity of acne vulgaris.

3. REVIEW OF LITERATURE

3.1. Chapter 1: Acne Vulgaris

Acne vulgaris is a chronic multifactorial, pleomorphic inflammatory skin disease of the pilosebaceous units which is characterized by formation of comedones and micro-comedones, erythematous papules and pustules. Nodules and pseudocysts are less common, and scarring occurs in some cases (*Layton, 2010*).

Studies suggest that the emotional impact of acne is comparable to that experienced by patients with systemic diseases, like diabetes and epilepsy. In conjunction with the considerable personal burden experienced by patients with acne, acne vulgaris also accounts for substantial societal and health care burden (*Dawson et al., 2012*).

3.1.1. Epidemiology:

3.1.1.1. Prevalence

Acne is estimated to affect 9.4% of the global population, making it the eighth most prevalent disease worldwide (*Tan and Bhat, 2015*).

3.1.1.2. Age:

Acne vulgaris is the most frequently diagnosed dermatosis in patients between 11 and 30 (*Bergler, 2014*). Acne

is most prevalent during the teenage years affecting over 80% of adolescents (*Tan and Bhat, 2015*). *Karciauskiene et al. (2014)* reported that the age of onset of acne is becoming earlier with 42% of those aged 7–9 years and 76% of those aged 10–12 years having acne. This earlier onset of acne might be due to puberty occurring at an earlier age (*Bhate and Williams, 2013*).

Although perceived as a teenage disease, acne may persist into adulthood (*Collier et al., 2008*). One population study in Germany found that 64% of those aged 20 to 29 years and 43% of those aged 30 to 39 years had visible acne (*Schafer et al., 2001*).

3.1.1.3. Sex:

Acne is more prevalent in girls at younger age ranges, with increasing prevalence in boys as they reach puberty. Male subjects also tend to have more severe acne. Following the teenage years, the prevalence in women again tends to be higher than in men (*KokuAksu et al., 2012*).

3.1.1.4. Race:

The prevalence of clinical acne varied with ethnicity: African Americans, Hispanics, Asians, Caucasians and Continental Indian women, at 37%, 32%, 30%, 24% and 23% respectively (*Perkins et al., 2011*). There are special populations in which the absence of acne may be instructive regarding pathogenesis as no acne was observed in two
