Acknowledgment

*First and foremost, many thanks for **God**, the kindest and beneficent.*

*I wish to express my great appreciation and thanks to **Prof. Dr. Yousseria M. Hassan Shetia** Prof. of Microbiology (Mycology), Faculty of Science, Ain-Shams University, for her continuous super-vision, unfailing guidance throughout the whole work, valuable advice and direction of this study.*

*My deep thanks to **Prof. Dr. Mona Sayed Shafei** Professor of Chemistry of Natural and Microbial Products, Department of Chemistry of Natural and Microbial Products, National Research Centre for her continuous super-vision and guidance especially during practical work, also her motherhood attitude, help and support.*

*I would like to extend my thanks to **Prof. Dr. Mahmoud M. Elaasser** Professor of Microbiology, Regional Center for Mycology and Biotechnology, Al-Azhar University for his patience, support and valuable help.*

I am also very thankful to staff members of The Regional Center for Mycology and Biotechnology, Al-Azhar University, staff members of Microbiology Department, Faculty of Science, Ain-Shams University.

Finally, my great thanks to my mother, father, my wife, sisters and all members in my family who had really supported me and suffered a lot during this study.

Dedication

I would like to dedicate this thesis to my mother, my father, my wife, sisters and my sons. To everyone who encouraged and supported me.

All my love and appreciation for them, my family.

Abstract

Riboflavin that commonly known as vitamin B2, is an important B vitamin for maintaining human health and it has been widely used in the fields of feed and food additives and pharmaceuticals. Certain microorganisms have the potential for natural production of vitamins and some fungi, bacteria and yeasts can produce riboflavin. So, the main purpose of current study was selection of the yeasts or fungi which are capable of producing riboflavin and then improving riboflavin production through utilization of different factors. Microorganisms are capable of producing vitamins, which are essential nutrients in the energy production. So, in this study, different strains were collected and cultivated in an enrichment medium for growth of yeasts and fungi. After purification, all colonies were examined for riboflavin production. Based on spectrophotometer and chromatographic analysis, 2 isolates could produce riboflavin. *Rhodotorula glutinis* isolate was selected as the best riboflavin producers by 49.313µg/ml. Then *Rhodotorula glutinis* isolate was selected to study on the effect of physiological and biochemical factors on production.

The production of Riboflavin was optimized by applying two factorial experiments. The first (Plakett Burman design) was to reflect the relative importance of fermentation medium components. The second (Box-Behnken design) was to optimize the physical factors affecting Riboflavin.

Immobilization of Riboflavin was performed by two methods namely: Covalent binding and Gel entrapment. The most

obvious benefit of the immobilization technique is the ability of continuous cycling, which provides a way to use them in continuous culture maintaining high cell population to achieve fast reaction rates.

Ultra Violet irradiation was chosen to improve the production of riboflavin using *Rhodotorula glutinis*.

Key words: Riboflavin, *Rhodotorula glutinis*, Plackett Burman design, Box-Behnken design, Immobilization and Ultra Violet irradiation.
