**ملاحظات:**

# **Diffuse Alopecia: Clinical, Trichoscopic, Histopathological and Immunohistochemical challenges in the Diagnosis**

Thesis

*Submitted for Partial Fulfillment of Master Degree  
in **Dermatology and Verology***

By

***Aisha Bashir Sheikh Adan***

*M.B.Ch.B Benader University, Mogadishu-Somalia*

Under Supervision of

**Prof. Dr. Hoda Ahmed Mohamed Moneib**

*Professor of Dermatology and Venereology  
Faculty of Medicine, Ain Shams University*

**Prof. Dr. Naglaa Samir Ahmed**

*Professor of Pathology  
Faculty of Medicine, Ain Shams University*

**Dr. Marwa Yassin Ahmed Soltan**

*Assistant Professor of Dermatology and Venereology  
Faculty of Medicine, Ain Shams University*

Faculty of Medicine  
Ain Shams University

2022

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قَالَ

لَسْبَّحَانَكَ لَا يَعْلمُ لَنَا  
إِلَّا مَا عَلَّمْتَنَا إِنَّكَ أَنْتَ  
الْعَلِيمُ الْعَظِيمُ

صدق الله العظيم

سورة البقرة الآية: ٣٢

# Acknowledgments

*First and foremost, I feel always indebted to **Allah** the Most Beneficent and Merciful.*

*I wish to express my deepest thanks, gratitude and appreciation to **Prof. Dr. Hoda Ahmed Mohamed Moneib**, Professor of Dermatology and Venereology, Faculty of Medicine, Ain Shams University, for her meticulous supervision, kind guidance, valuable instructions and generous help.*

*Special thanks are due to **Prof. Dr. Maglana Samir Ahmed**, Professor of Pathology, Faculty of Medicine, Ain Shams University, for her sincere efforts, fruitful encouragement.*

*I am deeply thankful to **Dr. Marwa Yassin Ahmed Soltan**, Assistant Professor of Dermatology and Venereology, Faculty of Medicine, Ain Shams University, for her great help, outstanding support, active participation and guidance.*

*I would like to express my hearty thanks to all my family for their support till this work was completed.*

**Aisha Bashir Sheikh Adan**

TE .....	Telogen effluvium
VIP .....	Vasoactive intestinal peptide

## INTRODUCTION

Diffuse hair shedding is a common complaint and a major challenge in the practice of dermatology, especially when it affects women. Female-pattern hair loss (FPHL), telogen effluvium (TE), and diffuse alopecia areata incognita (AAI) are its three main causes. It is often difficult to distinguish one from the other, and clinical data, laboratory findings, physical examination, procedures, and biopsy may be needed for a definitive diagnosis (*Werner and Brenner, 2012*).

Alopecia areata incognita (AAI) has been first described by **Rebora in 1987**. It is a subtype of alopecia areata, characterized by an acute intense and diffuse hair loss without the typical patches of alopecia. AAI is more common in patients under the age of 40, especially in those from 20 to 40 years of age with a typical strong female predominance. It shares clinical features with telogen effluvium, and it could also be misdiagnosed as androgenetic alopecia. Thus, a scalp biopsy is often required to confirm the clinical diagnosis (*Tosti et al., 2008*).

The histopathologic findings of AAI may be similar to the classical forms of the disease; however, the findings may be subtle and vary according to the disease stage (*Jameel et al., 2008*). The most consistent finding in acute AAI scalp biopsies is an inflammatory infiltrate around the terminal hair bulb. This infiltrate gradually decreases with chronicity and concentrates

around either only the miniaturized follicles or the follicular stela (streamers) (*Whiting, 2003*).

Additionally, a reversal in the anagen-telogen and terminal vellus ratios is always observed and maybe the only evidence suggesting the diagnosis in long-standing cases. Thus, from a pathological point of view, AAI should be suspected when high percentages of telogen hairs and/or miniaturized hairs are present even in the absence of a peribulbar lymphocytic infiltrate. The presence of a subtle lymphocytic infiltrate around miniaturized hairs in the papillary dermis strongly suggests the diagnosis (*Tosti et al., 2008*). These infiltrates may be present within the empty follicular fibrous tracts (stela), even without a concomitant peribulbar infiltrate (*Kolivras and Thompson, 2016*). *Miteva et al. (2012)* suggested that the main histopathologic clues for AA incognito include the presence of dilated infundibular openings and small basaloid aggregates of cells with round, irregular or polygonal shape, lack of hair shaft and no apoptosis in the outer root sheath, corresponding to small telogen follicles.

Videodermoscopy of hair and scalp is gaining popularity as a valuable tool in the differential diagnosis of hair loss. This method allows viewing of the hair and scalp at X70 to X160 magnifications (*Rudnicka et al., 2008*).

Since trichoscopy has become an important tool for diagnosis of various hair problems, it has been used also for

diagnosis of AAI from its mimickers. *Tosti et al. (2008)* examined 70 cases with AAI with videodermoscopy and found that the presence of numerous yellow dots and short re-growing hairs was a constant feature among AAI patients. Other features less frequently observed were the presence of dystrophic hairs, exclamation point hairs, and cadaverized hair. *Elghblawi (2016)* also supported the constant observation of numerous diffuse yellow dots of different size and uniform colors within the follicular orifices as an important feature in AAI. However, *Rakowska et al. (2009)* didn't share the same opinion and they found through analysis of different cases of alopecia that the presence of yellow dots in the “androgen-dependent” frontal area is the strongest criterion for female pattern androgenetic alopecia. In alopecia areata, yellow dots were less frequent and usually visible in long-lasting, not active alopecia, accompanied by cadaverized, dystrophic, or exclamation mark hairs.

The histological examination of sectioning will allow the detection of follicular pathology, even if it is focal. Moreover, it will yield quantitative data of follicular cycling, as well as morphometric evaluation of the hair follicles throughout their entire length, from the bulb to the acroinfundibulum. To achieve this, a 4-mm punch biopsy specimen including subcutaneous tissue is required (*Stefanato, 2010*). The vertical sections demonstrated the full thickness of the skin from the stratum corneum to deep subcutaneous fat in every section. However, they demonstrate only a few hairs in every section.

Any histological study requiring accurate vellus hair count and terminal vellus hair ratio requires the use of the transverse section (*Garcia and Poletti, 2007*).

The vertical sectioning is believed to be superior to horizontal sectioning and sufficient for routine diagnostic purposes (*Rakowska et al., 2009*). Irrespective of whichever level of transverse sectioning of the punch biopsy specimen is chosen, the ultimate goal is to reach the isthmic area. This is the site where the follicular units reside and afford the greatest number of diagnostic findings, including the opportunity to perform accurate follicular counts and follicular ratios (*Stefanato, 2010*).

The presence of T lymphocytes within the mononuclear infiltrate present AA is already well documented. *Kolivras and Thompson in 2016* investigated the possibility to differentiate cases of diffuse alopecia areata from pattern hair loss via immunohistochemical studying of CD3+ infiltrating T cells and found that the presence of CD3(+) lymphocytes within empty follicular fibrous tracts (stela), even without a concomitant peribulbar infiltrate, is a reliable histopathological clue in supporting a diagnosis of AA.

*Kamyab et al. (2019)* confirmed this finding and demonstrated that among four immunohistochemical markers (CD3, CD4, CD8, and CD20), CD3 is the most specific and sensitive test for differentiating of AA from androgenic alopecia.

In the view that AAI may mimic other disorders with acute diffuse hair shedding including female pattern hair loss (FPHL), telogen effluvium (TE) and the diagnosis of AAI represents a great challenge to identify, we will focus in this study on detection of clinical, trichoscopic, histopathological as well as immunohistochemical analysis for CD3 for analysis of cases with acute diffuse hair loss in females.

## **AIM OF THE WORK**

**W**e aimed to study the clinical, trichoscopic findings, histopathological in patients with acute diffuse hair shedding. Cases with a clinical or trichoscopic diagnosis of female pattern hair loss (FPHL), acute telogen effluvium (TE) and alopecia areata incognita (AAI) would be included. Immunohistochemistry analysis for CD3 would be done for possible differentiation between the three entities.
