# **Predication of Response to Disease Modifying Therapy in Multiple Sclerosis.**

*Thesis*

*Submitted for Partial Fulfillment of Master  
Degree in Neuropsychiatry*

*By*

**Abdelrahman Mohamed Abdellah Abdalla**

*M.B., B.Ch*

*Faculty of Medicine, Cairo University*

*Under Supervision of*

**Prof. Dr. Azza Abd El-Nasser**

*Professor of Neurology*

*Faculty of Medicine, Ain-Shams University*

**ASST . Prof. Dr. Mohamed Fouad**

*Assistant Professor of Neurology*

*Faculty of Medicine, Ain-Shams University*

**Dr. Mahmoud Saad Swelam**

*Lecturer of Neurology*

*Faculty of Medicine, Ain-Shams University*

*Faculty of Medicine  
Ain Shams University*

**2021**

# Acknowledgement

*First, I would like to thank **Allah** for blessing this work until it has reached its end, as a part of his generous guidance and help throughout my life.*

*I would like to express my sincere gratitude to **Prof. Dr. Azza Abd El-Nasser**, Professor of Neurology, Faculty of Medicine, Ain-Shams University for her support, encouragement and the tremendous effort he has done in the thorough revision of the whole work.*

*I would like also to extend my thanks to **Asst . Prof. Dr. Mohamed Fouad**, Assistant Professor of Neurology, Faculty of Medicine, Ain-Shams University for his sincere guidance throughout this work.*

*My sincere appreciation for **Dr. Mahmoud Saad Swelam**, Lecturer of Neurology, Faculty of Medicine, Ain-Shams University, who has taken the time and effort to read and modify this work.*

*My gratitude cannot be fulfilled without expressing my profound gratitude to my family , my wife, my son Omar and my colleagues who have been a rich source of concern and encouragement.*

*I also would like to thank the patients whom I learned a lot from their journey and their patience .*

## ABSTRACT

**Background:** Multiple sclerosis is an idiopathic inflammatory disease of the central nervous system and the second most common cause of disability in young adults. Choosing an effective treatment is crucial to preventing disability.

**Aim of the Work:** to identify predictors of DMT after one year of treatment.

**Patients and Methods:** In this retrospective study 150 patients with confirmed diagnosis of relapsing remittent MS was recruited from the MS unit at the Neurology departments from both Ain Shams University and Cairo University Students hospital. All of the study population were receiving either interferons or fingolimod. Modified Rio score was used to classify patient to responders and non responders.

**Results:** In this study 128 patients were found responders and 22 were found non responders. There was a significant difference between responders and non-responders regarding age of the participants. The age was significantly older in responders compared to non-responders (mean of  $32.37 \pm 7.248$  versus  $28.55 \pm 5.361$  years respectively;  $P = 0.019$ ). Gender was not a significant predictor of response to therapy. As regard the EDSS at the time of enrollment, it was significantly higher in non-responders [median (IQR) of 2 (1-3)] compared to responders [median (IQR) of 1 (0 – 2.5)] ( $P = 0.029$ ). Both total number of relapses throughout the course of disease and number of relapses in the last year were significantly higher in non-responders compared to responders ( $P < 0.001$ ). All of the studies MRI parameters including number of T2 lesions, black holes, current enhancing lesions, along with spinal lesions had no significant correlation with response to therapy. After performing regression analysis, modified Rio score was a significant predictor for response to DMT ( $P=0.001$ ). The longer the duration of therapy with DMT was predictive for response to DMT ( $P=0.032$ ). Also the compliance to medications ( $P=0.005$ ), and the lower total number of relapses throughout the course of disease ( $P=0.004$ ) were significant predictors for response to DMT among the study population.

**Conclusion:** In this study modified Rio score, the longer the duration of therapy with DMT, the compliance to medications, and the lower total number of relapses throughout the course of disease were found to be a significant predictors for response to DMT among the study population.

# INTRODUCTION

Multiple Sclerosis (MS) is a chronic inflammatory disease of the Central Nervous System (CNS) leading to demyelination and diffuse neurodegeneration in both brain and spinal cord (*Correale et al., 2019*)

MS is the most common progressive neurologic disease of young adults worldwide (*Wallin et al., 2019*)

MS diagnosis based on McDonald's diagnostic criteria, which link clinical manifestation with characteristic lesions demonstrated by magnetic resonance imaging (MRI), cerebrospinal fluid (CSF) analysis, and visual evoked potentials (*Kamińska et al., 2017*).

Subtypes of MS are considered important not only for prognosis but also for treatment decisions and include: relapsing remitting MS (RRMS), primary progressive MS (PPMS), secondary progressive MS (SPMS), and progressive relapsing MS (PRMS). (*Ghasemi et al., 2017*)

Approximately 87% of patients present with RRMS, Which characterized by acute attacks (relapses) followed by partial or full recovery (remission) (*Loma & Heyman ,2011*)

MS patients will require treatment with disease-modifying therapies (DMT) for rest of their lives after diagnosis (*Compston et al., 2008*).

The primary aim of treatment is to reduce disease activity to optimize neurologic reserve, cognition, and physical function (*Giovannoni et al., 2016*).

Numerous disease-modifying therapies exist that reduce relapses, reduce MRI activity, and delay disability, especially when initiated early in the disease when the inflammatory component of the disease is strongest (*Jones, 2016*).

The interferon (IFN) have been shown to reduce relapse rates and new MRI activity; they also delay disability progression as measured by the Expanded Disability Status Scale (EDSS) (*Calabresi et al., 2014*).

Oral fingolimod a sphingosine 1-phosphate (S1P) receptor agonist, is the first oral agent and the first in a novel class of DMTs to be approved for use in the US for the treatment of relapsing forms of MS a valuable emerging option for the treatment of adult patients with relapsing forms of MS (*Scott, 2011* ).

It is important to monitor treatment efficacy, as breakthrough disease can lead to irreversible neurologic disability, and transitioning into a progressive form of MS may close the therapeutic window of opportunity for the disease modifying therapies (*Rae-Grant et al., 2015*).

A baseline brain MRI should be performed with the initiation of a new disease-modifying therapy and a follow-up brain MRI to assess treatment response should be performed 6 months after starting a new disease-modifying therapy (and then every 6 months to 2 years) (*Trabouslee et al., 2015*).

Both clinical and MRI measures have proven useful in detecting disease activity and progression in patients with RRMS who are treated with DMT, and these two measures have been used in combination, to assess treatment response (*Sormani et al., 2013*).

## **AIM OF THE WORK**

The aim of this study is to identify clinical and radiological predictors of response to disease modifying therapies in patients with relapsing remittent multiple sclerosis after one year of therapy.
