HANAA ALY

Different Triggers of Anaphylaxis among Egyptian Children Attending Children's Hospital Ain Shams University

Thesis

**Submitted for Practical Fulfillment of Master
Degree in Pediatric**

By

Mousa Mohamed H. Mousa

M.B., B.Ch, Faculty of Medicine, Sirt University - Libya (2012)

Under Supervision of

Prof. Dr. Mohamed Hesham Mohamed Ezzat

Professor of Pediatrics

Faculty of Medicine, Ain-Shams University

Dr. Ghada Abdel Haleem Shousha

Lecturer of Pediatrics

Faculty of Medicine, Ain-Shams University

Dr. Hebat Allah Mohammed Salah Gabal

Lecturer of Community Environmental & Occupational Medicine

Faculty of Medicine, Ain-Shams University

**Faculty of Medicine
Ain Shams University
2020**

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

قَالَ

سُبْحَانَكَ لَا عِلْمَ لَنَا
إِلَّا مَا عَلَّمْتَنَا إِنَّكَ أَنْتَ
الْعَلِيمُ الْعَظِيمُ

صدق الله العظيم

سورة البقرة الآية: ٣٢

Acknowledgment

*First and foremost, I feel always indebted to **Allah**, the Most Kind and Most Merciful.*

*I'd like to express my respectful thanks and profound gratitude to **Prof. Dr. Mohamed Hesham Mohamed Ezzat**, Professor of Pediatrics, Faculty of Medicine, Ain-Shams University for his keen guidance, kind supervision, valuable advice and continuous encouragement, which made possible the completion of this work.*

*I am also delighted to express my deepest gratitude and thanks to **Dr. Ghada Abdel Haleem Shousha**, Lecturer of Pediatrics, Faculty of Medicine, Ain-Shams University, for her kind care, continuous supervision, valuable instructions, constant help and great assistance throughout this work.*

*I am deeply thankful to **Dr. Hebat-Allah Mohammed Salah Gabal**, Lecturer of Community Environmental & Occupational Medicine, Faculty of Medicine, Ain-Shams University, for her great help, active participation and guidance.*

*I would like to express my hearty thanks to all **my family** for their support till this work was completed.*

Last but not least my sincere thanks and appreciation to all patients participated in this study.

Mousa Mohamed

INTRODUCTION

According to World Allergy Organization (WAO) Anaphylaxis is defined as an acute, potentially life-threatening hypersensitivity reaction, involving the release of mediators from the mast cells, basophils and recruited inflammatory cells. It is defined by a number of signs and symptoms, alone or in combination, which occur within minutes to few hours, after exposure to a provoking agent (*Simons et al., 2011*). Anaphylaxis has sudden unpredicted onset; that reaches its peak within 5 to 30 minutes, and may, rarely, last for several days (*Sánchez-Borges et al., 2019*).

One in 5 children has a second reaction within 24 hours of the initial episode which is called a biphasic reaction. To decrease the likelihood of biphasic reaction, epinephrine must be given as soon as the diagnosis is settled. Presentation of anaphylaxis is variable among persons and even in the same person among different attacks (*Ninchoji et al., 2018*).

Reactions are typically uniphasic, however, in 0.4-15% of reactions they are biphasic in nature. The second phase usually occurs after an asymptomatic period of several hours (1-10h), but there may be a 24-hour delay. Protracted anaphylaxis may persist beyond 24 hours and their mortality rates are higher (*Fischer et al, 2018*).

Diagnosis of anaphylaxis is mainly clinical. WAO diagnostic criteria are the most widely accepted defining criteria. To the time being, there is no available, accurate and rapid diagnostic biomarker for anaphylaxis (*Sacco and Gonzalez-Estrada, 2018*).

Management of anaphylaxis is largely centered on resuscitation and administration of epinephrine (*Sacco and Gonzalez-Estrada, 2018*). Yet there is under treatment among a wide sector of junior medical staff, either due to lack of awareness about the diagnosis and the seriousness of anaphylaxis or due to lack of knowledge: when to give and when not to give epinephrine, the proper dose and the proper way of administration. Avoiding pitfalls in anaphylaxis diagnosis will help to establish rapidly effective treatment and would further reduce the rate of fatal event (*Parenta and Massimo, 2018*).

Studying the patterns of anaphylaxis in our environment will certainly contribute to a better understanding of this disease, as well as to a clearer comprehension of regional differences in morbidity and mortality factors.

AIM OF THE WORK

This work aims at evaluating the pattern of anaphylaxis among children attending Children's hospital, Ain Shams University through identifying the frequency, underlying triggers and clinical presentation of anaphylaxis and the possible mistakes in diagnosis and treatment.

REVIEW OF LITERATURE

Anaphylaxis:

The first recorded episode of anaphylaxis was described in hieroglyphic recordings from 2640 BC as the cause of death of an Egyptian pharaoh after a wasp sting. A more modern description of anaphylaxis was at 1902 during immunizing dogs with jellyfish toxin. The injection of small amounts of toxin in some animals precipitated a rapid onset of fatal or near-fatal symptoms. The term ‘anaphylaxis’ was derived from the Greek roots ‘ana’ (backward) and ‘phylaxis’ (protection or immunity) (*Chapman and Lalkhen, 2017*). Allergies are a growing health concern with a significant impact on quality of life and healthcare costs. It is critical to develop an appropriate care plan to deal with children’s allergies (*Elhassan et al., 2017*).

Definition of anaphylaxis:

The European Academy of Allergy and Clinical Immunology (EAACI) Nomenclature Committee proposed that anaphylaxis is a severe, life-threatening, multisystemic hypersensitivity reaction. Traditionally anaphylaxis was used to describe immunoglobulin E (IgE) - dependent events and ‘anaphylactoid reaction’ was used for IgE-independent reactions although both of these reactions are clinically indistinguishable (*Kim, 2018*).

Differences between anaphylaxis in adults and children:

Anaphylaxis occurs in all age groups, but most researches are focused on adults. Elicitors and clinical presentation of anaphylaxis in children and adolescents were shown to be different from those in adults, calling for specific research and targeted guidelines for pediatrics (*Simons and Sampson, 2015*).

Apparently, triggers of anaphylaxis are different between children and adults. Drug-induced (especially non-steroid anti-inflammatory drugs (NSAIDs) and antibiotics), idiopathic, and food-dependent exercise-induced anaphylaxis are more frequent in adults whereas food components are the leading cause of anaphylaxis in children (*Barzegar et al., 2010*).

Recommendations for the management of anaphylaxis are predominantly based on expert opinions and consensus. Evidence based guidelines were provided through WAO, American Academy of Allergy, Asthma and Immunology (AAAAI), EAACI and the National Institute of Allergy and Infectious Diseases (NIAID) (*Garvey et al., 2019*). Guidelines for adults and children stress on rapid diagnosis as being a key to optimal management, and management steps are almost the same in adults and children. Signs and symptoms of anaphylaxis for adults and children are summarized in table 1. Nevertheless,
