**Dexmedetomidine versus Fentanyl as Adjuvant to
Propofol Total Intravenous Anesthesia during
Endoscopic Retrograde Cholangial-
Pancreatography Procedure**

A Thesis

Submitted for partial fulfillment of Master degree in
Anesthesiology, Intensive Care and Pain Management

By

Nyanriak Thon Aguer

M.B.B.Ch., Faculty of Medicine, University of Bahr El Ghazal,
Khartoum – Sudan

Under Supervision of

Prof. Dr. Mostafa Kamel Reyad

Professor of Anesthesiology, Intensive Care and Pain Management
Faculty of Medicine, Ain Shams University

Assist. Prof. Dr. Sherif George Anis

Assistant Professor of Anesthesiology, Intensive Care and Pain Management
Faculty of Medicine, Ain Shams University

Dr. Mostafa Gamaledin Mahran

Lecturer of Anesthesiology, Intensive Care and Pain Management
Faculty of Medicine, Ain Shams University

**Faculty of Medicine
Ain Shams University
2021**

Acknowledgments

*First and foremost, I feel always indebted to **God**, the **Most Beneficent** and **Merciful**, Who gave me the strength to accomplish this work,*

*My deepest gratitude to **Prof. Dr. Mostafa Kamel Reyad**, Professor of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for his valuable guidance and expert supervision, in addition to his great deal of support and encouragement. I really have the honor to complete this work under his supervision.*

*I would like to express my great and deep appreciation and thanks to **Assist. Prof. Dr. Sherif George Anis**, Assistant Professor of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for his meticulous supervision, and his patience in reviewing and correcting this work,*

*I must express my deepest thanks to **Dr. Mostafa Gamaledin Mahran**, Lecturer of Anesthesiology, Intensive Care and Pain Management, Faculty of Medicine, Ain Shams University, for guiding me throughout this work and for granting me much of his time. I greatly appreciate his efforts.*

*Special thanks to my **Parents**, my **Husband** and all my **Family** members for their continuous encouragement, enduring me and standing by me.*

Introduction

Ensuring adequate sedation, analgesia and the patient's clinical stability by appropriate monitoring during endoscopic procedures has become extremely important over the last 10 years (*Hinkelbein et al., 2018*).

Various types of sedation and analgesia technique have been used during endoscopy procedures.

Providing an adequate regimen of sedation/analgesia might be considered an art, influencing several aspects of endoscopic procedures: the quality of examination, the patient's cooperation and the patient and physician's satisfaction with sedation (*Hinkelbein et al., 2018*).

The properties of a model sedative agent for endoscopy would include rapid onset and offset of action, analgesic and anxiolytic effects, ease of titration to desired level of sedation, rapid recovery and excellent safety profile.

Therefore, there is an impulse for development of new approaches to endoscopic sedation (*Lin, 2017*).

Endoscopic retrograde cholangio-pancreatography (ERCP) is commonly used in the management of many pancreatobiliary disorders. ERCP is the ideal method for extraction of common bile duct stones; it reduced the need for the more invasive surgical

procedures associated with high morbidity particularly in old age patients. ERCP with stent placement can be very effective for palliation of obstruction jaundice in pancreatic cancer patients (*Fanti and Teston, 2018*).

Endoscopy remains an unpleasant experience for most patients, the purpose of sedation in these patients is to relieve anxiety, discomfort or pain, and diminish memory of the events.

Conscious sedation enables patients to maintain their response to verbal and tactile stimuli without losing cardiovascular and ventilatory function.

The anaesthetic drugs that are usually used include benzodiazepines, ketamine, fentanyl, propofol, dexmedetomidine etc. Each class of anaesthetic drugs has different combination of anxiolytic, hypnotic, amnestic, and analgesic effects.

Selection of the most appropriate medication for specific patient requires consideration of many factors such as drug interaction.

The ideal sedative is free serious adverse effects; does not accumulate with repeated dosing.

In fact, most complications in GI endoscopy are related to sedation; including cardiopulmonary events such as

hypoxemia, hypoventilation, airway obstruction, apnoea, arrhythmia, hypotension, and vasovagal episodes.

The introduction and availability of different pharmaceutical agents such as propofol, fentanyl, and dexmedetomidine allow rapid induction of anaesthesia while enabling rapid recovery. Dexmedetomidine is a stereoisomer of medetomidine. It is a highly selective α_2 -agonist; eight times higher specificity for receptors compared with clonidine. It seems to have better hemodynamic parameters. It has a perioperative sedative, analgesic and anxiolytic properties similar to benzodiazepines but being α_2 adrenoceptor it has less side effect at doses $>0.5\mu\text{g/kg}$ this effect is dose- dependent. Dexmedetomidine is not a powerful antiemetic. It seems to be an alternative option for sedation during endoscopic outpatient procedures.

Propofol is a powerful sedative that has gained the role as the 'gold standard' for moderate to deep procedural sedation because of its rapid onset and termination of action, and the high level of satisfaction achieved among patients and physicians. Its most disadvantages is the risk of rapid change from conscious to deep sedation with the possibility of respiratory depression or airway obstruction leading to hypoxemia and cardiovascular depression.
