## Acknowledgments

*First and foremost, I feel always indebted to **Allah**, the **Most Beneficent** and **Merciful**, who gave me the strength to accomplish this work,*

*My deepest gratitude to **Prof. Dr. Magdy Hassan Kolaib**, Professor of Obstetrics and Gynecology, Faculty of Medicine, Ain Shams University, for his valuable guidance and expert supervision, in addition to his great deal of support and encouragement. I really have the honor to complete this work under his supervision.*

*I would like to express my great and deep appreciation and thanks to **Assist. Prof. Amr Helmy Yehia**, Assistant Professor of Obstetrics and Gynecology, Faculty of Medicine, Ain Shams University, for his meticulous supervision, and his patience in reviewing and correcting this work,*

*I must express my deepest thanks to **Assist. Prof. Mohamed Abd El Fattah El Senity**, Lecturer of Obstetrics and Gynecology, Faculty of Medicine, Ain Shams University, for guiding me throughout this work and for granting me much of his time. I greatly appreciate his efforts.*

*I can't forget to thank with all appreciation **Dr. Aliaa Mohamed Maaty**, Lecturer of Obstetrics and Gynecology, Faculty of Medicine, Ain Shams University, whom tirelessly and freely gave comments on various drafts of this piece of work; she was really a great support.*

*Special thanks to my **Parents** and all my **Family** members for their continuous encouragement, enduring me and standing by me.*

*✍ **Mohamed Ibrahim Ahmed Ibrahim Abdallah***

## Introduction

Placenta previa refers to the presence of placental tissue that extends over the internal cervical os (*ACOG, 2002*).

Placenta previa and placenta accreta are associated with high maternal and neonatal morbidity and mortality (*silver, 2015*).

The rates of placenta previa and accreta have increased and will continue to do so as a result of rising rates of caesarean deliveries, increased maternal age and use of assisted reproductive technology (ART) (*Bowman et al., 2014*).

The estimated incidence of placenta previa at term is 1 in 200 pregnancies (*Silver, 2015*).

Placenta accreta is a histopathological term first defined by Irving and Hertig in 1937, as the “abnormal adherence of the afterbirth in whole or in parts to the underlying uterine wall in the partial or complete absence of decidua”(*Irving and Hertig, 1937*).

Depending on the depth of villous tissue invasiveness, placenta accreta was subsequently subdivided by modern pathologists into ‘creta’ or ‘adherenta’ where the villi adheres superficially to the myometrium without interposing decidua; ‘increta’ where the villi penetrate deeply into the uterine myometrium down to the serosa; and ‘percreta’

where the villous tissue perforates through the entire uterine wall and may invade the surrounding pelvic organs, such as the bladder (*Fox et al., 2007*).

Thus, placenta accreta is a spectrum disorder ranging from abnormally adherent to deeply invasive placental tissue (*Luke et al., 1996*).

The current reported prevalence of placenta accreta ranges between 1 in 300 and 1 in 2000 pregnancies (*Benirschke et al., 2012*).

A cesarean delivery is always indicated when there is sonographic evidence of placenta previa and a viable fetus (*Zosmer et al., 2012*).

Advances in antenatal surveillance and early diagnosis have led to significant improvements in outcomes associated with placenta previa. Current surgical, anesthetic, and blood component therapeutics have also greatly improved maternal and fetal morbidity and mortality (*Lede'e et al., 2001*).

Nonetheless, placenta previa and placenta accreta continue to present clinical challenges with many associated complications. Hemorrhage remains the major complication of abnormal placentation, often necessitating premature delivery with its own perinatal impact. Emergent surgical intervention due to hemorrhage is associated with multiple

risks and may require hysterectomy to control blood loss (*Kastner et al., 2002*).

The blood supply of the uterus arises from the anterior division of the internal iliac artery which gives origin to the uterine artery (*Pelage et al., 1999*).

However, complex anastomosis between the aorta and branches of the internal iliac artery ensure adequate blood supply to the uterus such as the anastomosis between the ovarian artery which is a direct branch from the aorta and the uterine artery. Ligation of these arteries can dramatically decrease the blood flow to the uterus and hence arrest bleeding (*O’Leary, 1995*).

The stepwise uterine devascularization was successful as a conservative form of surgical management of placenta previa and accrete with preserving the uterus and fertility, saving patient’s life and minimizing major surgical interventions in all patients (*Palacios et al., 2004*).

Surgical uterine de-vascularization may represent the first-line procedure to control persistent hemorrhage during a cesarean section (*Kelekci et al., 2015*).

Optimal uterine devascularization may necessitate multiple arterial ligations; these include bilateral uterine arteries (O’Leary stitch), ovarian arteries and internal iliac arteries (*Walker et al., 2013*).
